The Expression of MRTF-A and AQP1 Play Important Roles in the Pathological Vascular Remodeling

Yong Jiang*

Abstract

**Background:** Objective Myocardin-related transcription factor (MRTF)-A is a Rho signaling-responsive co-activator of serum response factor (SRF). The purpose of this study is to investigate the role of MRTF-A and AQP1 (aquaporin 1) in pathological vascular remodeling. **Materials and Methods:** MRTF-A, AQP1 and neointima expression was detected both in the wire injured femoral arteries of wild-type mice and the atherosclerotic aortic tissues of ApoE−/− mice. Expression of ICAM-1, matrix metalloproteinase 9 (MMP-9) and integrin β1 were also assayed. The intercourse relationship between the molecules was investigated by interfering RNA and inhibitor assay. **Results:** MRTF-A and AQP1 expression were significantly higher in the wire injured femoral arteries of wild-type mice and in the atherosclerotic aortic tissues of ApoE−/− mice than in healthy control tissues. Both in wire-injured femoral arteries in MRTF-A knockout (Mkl1−/−) mice and atherosclerotic lesions in Mkl1−/−; ApoE−/− mice, neointima formation were significantly attenuated and the expression of AQP1 were significantly decreased. Expression of ICAM-1, matrix metalloproteinase 9 (MMP-9) and integrin β1, three SRF targets and key regulators of cell migration, and AQP1 in injured arteries was significantly weaker in Mkl1−/− mice than in wild-type mice. In cultured vascular smooth muscle cells (VSMCs), knocking down MRTF-A reduced expression of these genes and significantly impaired cell migration. Underlying the increased MRTF-A expression in dedifferentiated VSMCs were the down-regulation of microRNA-300. Moreover, the MRTF-A inhibitor CCG1423 significantly reduced neointima formation following wire injury in mice. **Conclusions:** MRTF-A could be a novel therapeutic target for the treatment of vascular diseases.

**Keywords:** Myocardin-related transcription factor (MRTF)-A - aquaporin 1 (AQP1)

Asian Pac J Cancer Prev, 16 (4), 1375-1383

Introduction

Myocardin-related transcription factor (MRTF)-A (Mkl1, Bsale or Mal) and MRTF-B (Mkl2) are transcriptional cofactors that associate with serum response factor (SRF). Myocardin-related transcription factor (MRTF)-B (Mkl2) is a transcriptional coregulator of the transcription factor SRF, which is a critical regulator of cell growth, differentiation, and apoptosis. MRTF-A and MRTF-B are primarily present in the cytoplasm and nucleus, respectively, and undergo rapid translocation between the two compartments in response to extracellular stimuli. The expression of MRTF-A and MRTF-B is regulated by various signaling pathways, including Rho family GTPases, which control the actin cytoskeleton and cell migration. MRTF-A and MRTF-B are able to translocate to the nucleus in response to stimulation with serum or other stimuli that promote Rho family GTPase activation and subsequent actin polymerization. MRTF-A and MRTF-B also regulate the expression of genes involved in cell proliferation, migration, and differentiation.

Aquaporins (AQPs) are a family of small integral membrane proteins related to the major intrinsic protein. They function as water channels in cells and tissues, and their expression is strongly associated with various diseases, including breast cancer, cardiovascular diseases, and diabetes. The expression of AQPs is regulated by multiple factors, including transcriptional regulators, microRNAs, and post-translational modifications. In this study, we investigate the role of MRTF-A and AQP1 in pathological vascular remodeling and their potential as therapeutic targets for vascular diseases.
of the MRTF-A gene that enhances the gene expression (Jin et al., 2010) reported that MRTF-A knockout mice were born in anticipated Mendelian ratios, whereas some studies reported that MRTF-A knockout mice were born at less than the anticipated Mendelian ratio, which they attributed to fetal loss due to heart failure (Nakamura et al., 2010). In both groups, however, live born MRTF-A knockout pups showed no obvious gross abnormality or cardiovascular defect under normal conditions, except for a defect in maternal lactation due to impaired phenotypic modulation of mammary gland myoepithelial cells (Jeon et al., 2010). Other studies indicated that MRTF-A might be an important regulator of mammary gland and can be involved in cancer metastasis and that Histone methyltransferase SMYD3 can promote MRTF-A-mediated transactivation of MYL9 and migration of MCF-7 breast cancer cells (Luo et al., 2014).

In the present study, we investigated the potential roles of MRTF-A in the pathological processes underlying vascular proliferative diseases and the possible mechanisms involved in it. The purpose of our study is to provide experimental evidence for clinical target therapy of vascular diseases.

Materials and Methods

Plasmids
-930 bp MRTF-A(-184C)-luc (MRTF-A-luc), ICAM-1-luc, ICAM-1 CarG-mut-luc and 3xCarG-luc were described previously (Weinl et al., 2013). Expression vectors used in the experiments were described previously (Ni et al., 2013). MRTF-A 3’UTR-luc and mut MRTF-A 3’UTR-luc were respectively generated by inserting the MRTF-A 3’UTR containing wild type or mutated miR-300 target sequences downstream of the luciferase gene in a pmIR-REPORTER kit miRNA reporter expression vector (Ambion). -5500 bp MRTF-A-luc was generated by inserting 5500 bp of the 5’-FR of MRTF-A gene upstream of the luciferase gene in pGL4 vector (Promega).

Animal experiments
MRTF-A-/- mice were kindly provided from Dr EN Olson (The University of Texas, Southwestern Medical Center at Dallas), ApoE-/- and MRTF-A-/- mice (C57BL/6 background) were cross-bred. The animal care and all experimental protocols were reviewed and approved by the Animal Research Committee at Jilin Medical College.

Cell culture and transfection
RAVSMCs (Cell Applications, Inc.), A7r5 (DS Pharma Biomedical), NIH3T3 and COS7 cells were maintained in DMEM supplemented with 10% FCS. Co-transfection of RAVSMCs with 3xCarG-luc plus expression plasmids encoding MRTF-A (1 ng) and STARS (100 ng), or with MRTF-A-luc plus expression plasmids encoding AQP1 and MRTF-A (0, 1 or 10 ng each) was accomplished using FuGene6 (Roche). pRL-TK (Roche) was included in all transfections as an internal control. MiRIDIAN microRNA mimic for miR-300, miRIDIAN microRNA hairpin inhibitor for miR-300 or a negative control for each (Thermo Scientific) was transfected into RAVSMCs grown in 6-cm dishes using Dharmafect2. MAVSMCs were obtained as previously reported (Shen et al., 2011).

Mouse vascular injury
Vascular wire injury was induced in femoral arteries of male C57BL/6 wild-type or Mk1-/- mice at 8-10 weeks of age, as described previously (Davis-Dusenbery et al., 2011). LNA oligonucleotide anti-miR-300 microRNA inhibitor or LNA microRNA inhibitor negative control (20 mg/kg) (50-FAM prelabelled, Exiqon) was injected into sham-operated or injured femoral arteries from the muscular branch using a syringe with 29 gauge needle (TERUMO). Atherosclerosis lesions were analysed by en-face analysis of the whole aorta and quantified by cross-sectional analysis of the proximal aorta.

Quantification of neointimal hyperplasia
We harvested the femoral and carotid arteries 4 weeks after wire injury, unless otherwise indicated. Digitalized images were analysed using image analysis software (Image J, NIH), and the intimal and medial areas were recorded. The average of the neointima/media ratios in FIVE serial sections was designated as the value to represent each individual.

Wound healing experiments
The cells (5×10³) were seeded in 6-well plates and after 24 h, when the cells had grown by 90-100%, they were scraped with a pipette tip to generate straight wounds. To ensure documentation of the same region, the wells were marked across the wounded area. The medium was replaced with a serum free medium (RPMI-1640, Wisent Inc., St-Bruno, QC, Canada) and the cells were treated with a medium containing 1 mM mitomycin to inhibit cell division. Phase contrast images were recorded under an inverted microscope (Nikon ECLIPSE Ti-E, Nikon, Kobe, Japan) at the time of wounding, 0 h, and at 24 h. The untreated cells served as controls.

Analysis of atherosclerotic lesion area in ApoE-/- mice
Mkl1-/-; ApoE-/- and Mkl1A-/-; ApoE-/- mice were fed normal chow for 4 weeks beginning when the mice were 4 weeks old. Then beginning when they were 8 weeks old, they were fed a high cholesterol diet (F2HFD1, Oriental Biotechnology) for 8 weeks. Atherosclerotic lesions were analysed by en-face analysis of the whole aorta and quantified by cross-sectional analysis of the proximal aorta.

PCR
RNA isolation and reverse transcription were performed as previously described (Wang et al., 2012). Oligonucleotide primer sequences were as follows: β-actin (264bp), forward: 5’-GAG ACC TTC AAC ACC CCA GCC-3’, reverse: 5’-AAT GTC AC G CAC GATT TCC C-3’; MRTF-A (201bp), forward: 5’-TCC CCA TCG CCA TCC CC-3’ reverse: 5’-CAC CAT GGC TTC GGC TTGG-3’. For all the above genes, amplification was performed under the same cycling conditions (1 minute at 94°C, 50 seconds at 57°C, 1 minute at 72°C), except the number of cycles that were specified for each gene (32 for MRTF-A).

Western blot and Immunoprecipitation
Cells were harvested at specific times after treatment
with regents as indicated in each experiment. Cells were mixed with loading buffer and subject to electrophoresis. After electrophoresis, proteins were transferred to polyvinyl difluoride membranes (Pall Filtron) using a semidyry blotting apparatus (Phar基本) and probed with mouse mAbs, followed by incubation with peroxidase-labeled secondary antibodies. Detection was performed by the use of a chemiluminescence system (Amersham) according to the manufacturer’s instructions. Then membrane was stripped with elution buffer and reprobed with antibodies against the nonphosphorylated protein as a measure of loading control. Controls for the immnoprecipitation used the same procedure, except agarose beads contained only mouse IgG.

Luciferase assay
Forty-eight hours after transfection, the cells were rinsed in PBS. Experiments for each treatment were performed in triplicate. Luciferase activity was assessed using the dual-luciferase reporter assay system (Promega, WI, USA) with a luminometer (Promega, WI, USA). The luciferase activity after cell lysis was measured and then normalized to the activity of renilla luciferase driven by the constitutively promoter in the pRL vector. Basal promoter activity was measured relative to the activity observed with the pGL3 vector alone.

RNA-i experiments
The si-RNA sequence targeting human MMP-9 (from mRNA sequence; Invitrogen online) corresponds to the coding region 377-403 relative to the first nucleotide of the start codon (target=5'-AAC ATC ACC TAT TGG ATC CAA ACT AC-3'). Computer analysis using the software developed by Ambion Inc. confirmed this sequence to be a good target. si-RNAs were 21 nucleotides long with symmetric 2-nucleotide 3’ overhangs composed of 2’-deoxymethylene to enhance nuclease resistance. The si-RNAs were synthesized chemically and high pressure liquid chromatography purified (Genset, Paris, France). Sense si-RNA sequence was 5'-CAU CAC CUA UUG GAU CCA AdT dT-3'. Antisense si-RNA was 5'-UUG GAU CCA AUA GGU GAU GdT dT-3'. For annealing of si-RNAs, mixture of complementary single stranded RNAs (at equimolar concentration) was incubated in annealing buffer (20 mM Tris-HCl pH 7.5, 50 mM NaCl, and 10 mM MgCl2) for 2 minutes at 95°C followed by a slow cooling to room temperature (at least 25°C) and then proceeded to storage temperature of 4°C. Before transfection, cells cultured at 50% confluence in 6-well plates (10 cm2) were washed two times with OPTIMEM 1 without FCS for 1 hour. Then, cells were transfected with polyvinyl difluoride membranes (Pall Filtron) using a semidyry blotting apparatus (Phar基本) and probed with mouse mAbs, followed by incubation with peroxidase-labeled secondary antibodies. Detection was performed by the use of a chemiluminescence system (Amersham) according to the manufacturer’s instructions. Then membrane was stripped with elution buffer and reprobed with antibodies against the nonphosphorylated protein as a measure of loading control. Controls for the immnoprecipitation used the same procedure, except agarose beads contained only mouse IgG.

Increased expression of MRTF-A in femoral arteries after wire injury
To explore the potential role played by MRTF-A during pathological vascular remodeling, we initially compared the expression of AQP1, MRTF-A and MRTF-B mRNA between femoral arteries subjected to wire injury or to a sham operation. As seen previously (Du et al., 2009), levels of AQP1 mRNA were significantly up-regulated in similar conditions (20 nM). The efficiency of silencing was 80% in our assay.

Statistical analysis
Results are expressed as mean±standard deviation. Data were analysed using the unpaired two-tailed student’s t test and the log rank test. P values of p<0.05 were considered significant.

Results
Increased expression of MRTF-A in femoral arteries after wire injury
Figure 1. Increased Expression of MRTF-A in Femoral Arteries after Wire Injury in Mice. (A) Real-time RT–PCR analysis showing relative levels of AQP1, MRTF-A and MRTF-B mRNAs (normalized to Actin mRNA) in femoral arteries 2 weeks after wire injury (injury) (n=6 each). The relative mRNA level in sham-operated arteries (sham) was assigned a value of 1.0. (B) Representative western blots and PCR showing AQP1, MRTF-A and MRTF-B in wire-injured and sham-operated femoral arteries (2 weeks after injury). The relative protein levels (normalized to Actin) of AQP1, MRTF-A and MRTF-B were quantified and their expression levels were compared to Actin (1.0). The relative protein levels in the sham-operated arteries were assigned a value of 1.0. (D) Immunohistochemical analysis of MRTF-A expression in sham-operated and wire injured femoral arteries. The expression of MRTF-A and AQP1 play important roles in the pathological vascular remodeling.
femoral arteries 2 weeks after wire injury, while levels of MRTF-B mRNA were not significantly affected (Figure 1A). By contrast, expression of MRTF-A mRNA was significantly increased in injured arteries, as compared to sham-operated arteries (Figure 1A). Western blot and PCR analysis using specific antibodies for AQP1, MRTF-A and MRTF-B, respectively, clearly showed that the level of AQP1 protein was increased in injured arteries, whereas MRTF-A protein was significantly increased (Figure 1B and C). Immunohistochemical analysis showed that cells positively stained for MRTF-A were located mainly in the neointima of injured arteries (Figure 1D). Moreover, in serial sections stained for α-smooth muscle actin (αSMA), most of the cells that positively stained for MRTF-A also positively stained for αSMA (Figure 1D).

**Attenuated vascular remodelling after wire injury in MRTF-A knockout mice**

To further evaluate the function of MRTF-A during vascular remodeling, next we performed wire injury in the femoral arteries of MRTF-A knockout (Mkl1<sup>-/-</sup>) mice. As previously reported (Hanna et al., 2009), the Mkl1<sup>-/-</sup> mice were viable, fertile and showed no significant gross abnormalities or cardiovascular defects under normal conditions. There was no difference in blood pressure or heart rate between wild-type and Mkl1<sup>-/-</sup> mice (Figure 2A). Femoral arterial expression of AQP1 mRNA was significantly higher in Mkl1<sup>-/-</sup> mice 2 weeks after wire injury than in sham-operated arteries, just as was observed with wild-type mice (Figure 2B). On the other hand, neointima-to-medial ratios determined 4 weeks after wire injury were significantly smaller in Mkl1<sup>-/-</sup> mice than in wild-type mice (Figure 2C). Four weeks after wire injury, the neointimal area comprised cells positively stained for αSMA was markedly smaller in Mkl1<sup>-/-</sup> mice than in wild-type mice (Figure 2D). Immunohistochemical analysis in serial sections stained for SM-MHC showed overlap with αSMA-positive cells, suggesting that a reduction in the

numbers of dedifferentiated VSMCs within the neointima is largely responsible for the reduction in the neointima-to-medial ratios seen in Mkl1+/− mice (Figure 2D). Indeed, the numbers of Ki-67-positive proliferating cells within the injured vessels were also significantly lower in Mkl1+/− mice than in wild-type mice (Figure 2E). In addition, because multiple cell types other than dedifferentiated VSMCs can contribute to neointima formation and to the vascular remodeling process, we also stained the tissue for endothelial cell (CD31) and macrophage (Mac3) markers. The relative numbers of CD31-positive and Mac3-positive cells in the injured arteries did not differ between wild-type and Mkl1+/− mice (Figure 2F), which indicates that a reduction in the number of αSMA-positive dedifferentiated VSMCs contributes to the attenuation of vascular remodeling in wire-injured Mkl1+/− mice. It showed no significant difference in the semi-quantitative CD31-positive scores and the relative numbers of Mac3-positive cells between Mkl1+/− and Mkl1+/− mice 4 weeks after wire injury (Figure 2G and 2H).

**Loss of MRTF-A attenuates atherosclerotic lesions in APOE−/− mice**

We next sought to analyse MRTF-A expression in a model of a different type of vascular disorder. ApoE−/− mice are prone to atherosclerotic lesions, to which both dedifferentiated VSMCs and infiltrating inflammatory cells contribute. MRTF-A gene expression was significantly up-regulated in aortic tissues containing atherosclerotic lesions in ApoE−/− mice fed a high cholesterol diet for 8 weeks (from 8 to 16 weeks of age), as compared to normal wild-type aortic tissues in age-matched mice (Figure 3A). By contrast, AQP1 gene and MRTF-A gene expression...
was significantly up-regulated in atherosclerotic aortas, compared to normal aortas (Figure 3A). Consistent with that finding, cells positively stained for MRTF-A were observed within atherosclerotic lesions in the proximal aorta of ApoE⁻/⁻ mice (Figure 3B). RT-PCR analysis showed that the expression of AQP1 in atherosclerotic aorta had no significant difference between Mkl1⁻/⁻; ApoE⁻/⁻ mice and Mkl1⁺/+; ApoE⁻/⁻ mice (Figure 3C). En-face analysis of the global progression of atherosclerotic lesions throughout the aorta revealed that the aortas of Mkl1⁻/⁻; ApoE⁻/⁻ mice contained smaller atherosclerotic lesions than those of Mkl1⁺/+; ApoE⁻/⁻ mice (Figure 3D). Furthermore, cross sectional analysis of the proximal aorta revealed the average lesion area at the aortic root of Mkl1⁻/⁻; ApoE⁻/⁻ mice (2.5%) to be significantly smaller than at the aortic root of Mkl1⁺/+; ApoE⁻/⁻ mice (11.8%, p<0.05 versus Mkl1⁻/⁻; ApoE⁻/⁻) (Figure 3E). Besides, we also found the moving ability of Mkl1⁻/⁻; ApoE⁻/⁻ mice to be significantly slower than at the aortic root of Mkl1⁺/+; ApoE⁻/⁻ mice (p<0.05 versus Mkl1⁻/⁻; ApoE⁻/⁻) (Figure 3F).

MRTF-A is necessary for acquisition of migratory capacity in dedifferentiated VSMCs

SRF controls cellular migration capacity in various cell types, including dedifferentiated VSMCs by regulating the expression of several target genes, including the genes encoding ICAM-1, MMP9 and integrin β1 (Du et al., 2009; Wang et al., 2013; Weinl et al., 2013). We therefore examined the expression of these SRF-target genes in wire-injured femoral arteries. We found that 2 weeks after wire injury there was significantly less expression of ICAM-1, MMP9 and integrin β1 genes in the injured femoral arteries of Mkl1⁺/+; ApoE⁻/⁻ mice than control Mkl1⁻/⁻; ApoE⁻/⁻ mice (Figure 4A). The levels of ICAM-1, MMP9, integrin β1 and AQP1 were significantly reduced after interfering with MRTF-A (Figure 4B). Over-expression of MRTF-A stimulated ICAM-1 promoter activity in an SRF-dependent manner in both primary rat aortic VSMCs (RAVSMCs) and NIH3T3 fibroblasts (Figure 4C), whereas interfering with MRTF-A reduced ICAM-1 promoter activity in RAVSMCs (Figure 4D). This supports the conclusion that MRTF-A regulates the expression of SRF-target genes in dedifferentiated VSMCs. Furthermore, interfering with MRTF-A significantly impaired PDGF-BB-induced RAVSMC migration (Figure 4E). Because SRF is also known to control cellular migration, we examined the effect of MRTF-A interference on RAVSMC migration, and found that interfering with MRTF-A significantly reduced serum-induced RAVSMC migration (Figure 4F).

MRTF-A was a direct target of miR-300

Luciferase reporter gene assay of miR-300 3’ UTR wild type and mutant showed that in 3’ UTR wild type, miR300 decreased the luciferase activity of MRTF-A, but in 3’ UTR mutant, miR300 had no influence, which indicated that miR300 can reduce the expression of MRTF-A (Figure 5A). Western blot assays confirmed that MRTF-A expression were down-regulated by miR-300 (Figure 5B). MRTF-A expression was significantly increased in MRTF-A -transfected cells (CMV-HA-MRTF-A) compared with that in control cells (CMV-HA) (Figure 5C). The numbers of viable cells determined by cell count 72 hours after co-transfection with miR-300 and CMV-HA- MRTF-A vector didn’t show significant difference (Figure 5D). In wound healing experiment, the migration distance of VSMCs transfected with miR300 was shorter than that without miR300 (Figure 5E).

Pharmacological inhibition of MRTF-A activity attenuates adverse vascular remodelling after wire injury

The results presented raise the possibility that MRTF-A is a novel therapeutic target for the treatment of vascular disease. Recently, a small molecule (CCG-1423) was found to inhibit Rho pathway-mediated SRF activation. CCG-1423 appears to inhibit the interaction between SRF and MRTF-A at a point upstream of the DNA binding.

Figure 6. CCG-1423, an MRTF-A inhibitor, attenuated neointima formation induced by wire injury in mouse femoral arteries. (A) CCG-1423 diminished the nuclear accumulation of endogenous MRTF-A induced by 20% FCS in RAVSMCs. Cells were stained with anti-MRTF-A antibody (green) and DAPI (blue), (B) CCG-1423 significantly inhibited MRTF-A-induced SRF activity in RAVSMCs. Graphs show the relative luciferase activities of 3xCarG-luc. STARS: expression plasmid encoding striated muscle activator of Rho signaling. Data were obtained from two experiments performed in quintuplicate. (C) PDGF-BB-induced migration was assessed in RAVSMCs treated without or with 0.1 mm (+) or 1 mm (++) of CCG-1423. Data were obtained from two experiments performed in sex tuplicate. (D) FCS-induced migration was assessed in RAVSMCs treated without or with 0.1 mm (+) or 1 mm (++) of CCG-1423. Data were obtained from two experiments performed in quadruplicate. (E) Effect of CCG-1423 on neointima formation in wire-injured femoral arteries in mice. Graph showing the neointima (NI)-to-media (M) ratio in wire-injured arteries from mice treated without (control) or with CCG-1423 (n=3 in control group and 4 in CCG1423 group). (F) Graphs showing the relative (%) area of atherosclerotic lesions in cross-sections of proximal aorta from ApoE⁻/⁻ mice fed a high cholesterol diet and treated with or without CCG-1423 for 6 weeks (n=3 in control group and 4 in CCG1423 group). ** p<0.01. (G) Effect of an SNP in the promoter region of MRTF-A gene (-184C>T) on the promoter activity in RAVSMCs. Relative activities of -930 bp MRTFA(-184C)-luc and -930 bp MRTF-A(-184T)-luc in two different experiments performed in quadruplicate are shown. All graphs are shown as means±s.e.m. ** p<0.01.
Although the site of inhibition and its selectivity is not yet precisely defined, it was recently shown that CCG-1423 blocks nuclear translocation of MRTF-A, thereby inhibiting MRTF-A-mediated effects on SRF transcription, at least in part (Hanna et al., 2009; Jin et al., 2010). In addition, we confirmed that CCG-1423 blocks serum-induced nuclear accumulation of endogenous MRTF-A in RAVSMCs (Figure 6A). CCG-1423 also significantly blocked SRF activity induced by co-expression of striated muscle activator of rhod signaling (STARS) and MRTF-A in RAVSMCs (Figure 6B). STARS is an actin-binding protein that activates SRF by inducing nuclear accumulation of MRTF-A. Both CCG-1423 and MRTF-A knockdown similarly inhibited STARS-induced activation of SRF in RAVSMCs. Similarly to knocking down MRTF-A, CCG-1423 significantly reduced the migration capacities of RAVSMCs (Figure 6C and D). When we then treated mice subjected to femoral artery wire injury with CCG-1423 (0.15 mg/kg intraperitoneally for 3 weeks), we found that CCG-1423 significantly attenuated the progression of vascular remodeling in arteries 3 weeks after injury (Figure 6E). Furthermore, as shown by Figure 6F, the relative (%) area of atherosclerotic lesions in cross-sections of proximal aorta from ApoE<sup>−/−</sup> mice fed a high cholesterol diet that treated with CCG-1423 for 6 weeks was significantly decreased (Figure 6F). After determined the effect of an SNP in the promoter region of MRTF-A gene (-184C>T) in the promoter activity in RA VSMCs, we found that the relative activitie of -930 bp MRTFA(-184C)-luc were significantly lower than that of -930 bp MRTF-A(-184T)-luc (Figure 6G).

Discussion

Angiogenesis is an important physiological process in which new blood vessels are generated by sprouting of existing ones. Dysregulated angiogenesis is implicated in many human diseases, including cancer and retinopathies (Du et al., 2009; Hanna et al., 2009). During angiogenesis, endothelial tip cells at the angiogenic front form numerous filopodia and guide vascularization, whereas stalk cells located behind tip cells are involved in proliferation and vessel extension (Lockman et al., 2007).

In the present study, we used two vascular injury models (femoral artery injury and diet induced atherosclerosis in APOE<sup>−/−</sup> mice) in Mk1<sup>−/−</sup> mice to elucidate the roles played by MRTF-A in pathological vascular remodeling. We initially found that expression of MRTF-A and AQP1 were significantly increased in injured arteries and aortic tissues containing atherosclerotic lesions in ApoE<sup>−/−</sup> mice. In each model, neointima formation or atherosclerotic lesions were significantly smaller in Mk1<sup>−/−</sup> mice than in the respective controls. The expression of ICAM-1, MMP-9, integrin β1 genes and AQP1, which are key regulators of cellular migration, was significantly diminished in the injured arteries of Mk1<sup>−/−</sup> mice. However, AQP1 can promote tumour angiogenesis by allowing faster endothelial cell migration and sustaining an active endothelium (Nicchia GP et al., 2013). Knocking down MRTF-A in RAVSMCs reduced expression of these genes in response to extracellular stimuli, which significantly impaired cell migration. Recent studies revealed that we can repress the progression and metastasis of cancer cell via MRTF-A/B, which can activate the transcription of several actin cytoskeletal/focal adhesion genes SRF dependently to enhance the formation of stress fibers and focal adhesions (Yoshio T et al., 2010). These results demonstrate that induced expression of MRTF-A is crucial for acquisition of the capacity to migrate in response to environmental stress in dedifferentiated VSMCs. We also found that MRTF-A gene expression in VSMCs is, at least in part, regulated by miR-300 (Lagna et al., 2007; Parmacek et al., 2007). Finally, we showed that a small molecule inhibitor of MRTF-A, CCG-1423, significantly reduced neointima formation following wire injury to mouse femoral arteries. Collectively, these results demonstrate that induction of MRTF-A plays a key role in vascular remodeling by maintaining SRF activity, thereby conferring a capacity for migration in response to extracellular stimuli on dedifferentiated VSMCs. MRTF-A is thus a potentially useful therapeutic target that may be more specific and efficient than the upstream Rho family GTPase, which can affect diverse intracellular signaling events.

The ability of MRTF-B to transduce Rho signaling into the nucleus is much weaker than that of MRTF-A (Staus et al., 2007; Hanna et al., 2009) so that Rho family signaling is almost exclusively confined to regulating contraction through modifying Ca<sup>2+</sup> sensitivity in the cytosol (Hinson et al., 2007). Because MRTF-A is shuttled between the cytosol and nucleus (Lockman et al., 2004), where it activates SRF downstream of Rho family GTPase-actin signaling, in dedifferentiated VSMCs extracellular stimuli activating Rho GTPase signaling can substantively affect cellular proliferation and migration by modulating SRF activity (Smith et al., 2014; Dbouk et al., 2014). Loss or inhibition of MRTF-A reduced stimulus-induced cell migration, making cells static (Mah et al., 2014; Kanavi et al., 2014). This suggests that the expression of MRTF-A regulated by miR-300 regulates the plasticity of effectors downstream of Rho family signaling, thereby contributing to phenotypic modulation of VSMC during vascular remodeling.

In addition to the classical concept that dedifferentiated intimal VSMCs are derived from medial VSMCs, recent evidence raises the possibility that VSMC progenitor cells in the circulation or adventitia also contribute to intimal VSMCs (Bizenjima et al., 2014; da Cunha Morales Álvares et al., 2014). We have not addressed the role of MRTF-A in the process of intimal VSMC differentiation from such progenitor cells in this study. In that context, however, MRTF-A has been shown to be involved in the differentiation of mesenchymal stem cells into VSMCs (Mah et al., 2014). Thus, MRTF-A may also play an important role in the molecular processes underlying migration, proliferation and differentiation of VSMC progenitor cells into intimal VSMCs during vascular remodeling.

Recently, human genetic screening to identify novel susceptibility loci for CAD using micro-satellite markers and SNP analysis revealed that an SNP in the promoter region of the MRTF-A gene (-184C>T) is associated...
with susceptibility to CAD (Garcia et al., 2014; Buckinx et al., 2014). Moreover, functional analysis suggested that heightened MRTF-A expression is associated with increased susceptibility to CAD (Maki et al., 2014; Moris et al., 2014). We observed that the MRTF-A promoter containing -184T, which is associated with high CAD susceptibility, showed significantly stronger transcriptional activity than the wild-type promoter in cultured VSMCs. These observations further support the conclusion that MRTF-A is crucially involved in pathological vascular remodeling underlying the development of vascular diseases (Mooren et al., 2014; Yoshida et al., 2014), and imply that MRTF-A is a potentially useful therapeutic target for prevention of the progression of vascular diseases.

Generally speaking, inhibition of MRTF-A expression is key to pathological remodeling underlying vascular disorders, as it sustains the SRF activity necessary for dedifferentiated VSMCs to acquire the capacity to migrate in response to extracellular stimuli. Our findings suggest that the expression of MRTF-A is mediated, at least in part, by microRNA (miR)-300 and contributes to the phenotypic modulation of VSMCs during vascular remodeling. These results point to MRTF-A as a potentially useful therapeutic target for the treatment of vascular diseases.
