RESEARCH ARTICLE

CD26: A Prognostic Marker of Acute Lymphoblastic Leukemia in Children in the Post Remission Induction Phase

Atheer Awad Mehde1,2 Faridah Yusof1 Wesen Adel Mehdi3,* Jwan Abdulmohsin Zainulabdeen4

Abstract

Background: ALL is an irredeemable disease due to the resistance to treatment. There are several influences which are involved in such resistance to chemotherapy, including oxidative stress as a result of the generation of reactive oxygen species (ROS) and presence of hypodiploid cells. Cluster of differentiation 26 (CD26), also known as dipeptidyl peptidase-4, is a 110 kDa, multifunctional, membrane-bound glycoprotein. Aim and objectives: The aim of this study was to evaluate the clinical significance of serum CD26 in patients with acute lymphoblastic leukaemia patients in the post remission induction phase, as well as the relationship between CD26 activity and the oxidative stress status. Materials and Methods: CD26, total antioxidant status (TAS), total oxidant status (TOS), and oxidative stress index (OSI), in addition to activity of related enzymes myeloperoxidase, glutathione-s-transferase and xanthine oxidase, were analysed in sixty children with acute lymphoblastic leukaemia in the post remission induction phase. Results: The study showed significant elevation in CD26, TOS and OSI levels in patients with acute lymphoblastic leukaemia in the post remission induction phase in comparison to healthy control samples. In contrast, myeloperoxidase, glutathione-s-transferase and xanthine oxidase activities were decreased significantly. A significant correlation between CD26 concentration and some oxidative stress parameters was evident in ALL patients. Conclusions: Serum levels of CD26 appear to be useful as a new biomarker of oxidative stress in children with acute lymphoblastic leukaemia in the post remission induction phase, and levels of antioxidants must be regularly estimated during the treatment of children with ALL.

Keywords: Acute lymphoblastic leukemia (ALL) - CD26 - glutathione-s-transferase

Asian Pac J Cancer Prev, 16 (12), 5059-5062
(ROS), inhibitors of enzyme reactions including pseudosubstrates and modifiers of the active sites of enzyme inhibitors of ROS generating enzymes, for instance, active in expression of enzyme proteins and assembly of enzyme components and inducers of anti-oxidative enzymes. Radical scavengers have been considered as promising candidates as chemopreventors because they have been found to strongly inhibit oxidative reactions both in vitro and in vivo. Therefore, dietary radical scavengers such as a-tocopherol, ascorbic acid, β-carotene and simple phenolics have attracted a great deal of attention (Huang et al., 1992). The aim of this study was to estimate of the CD26 activity in patients with acute lymphoblastic leukemia patients at post remission induction phase, and the relationship between CD26 activity and related oxidative stress enzymes.

Materials and Methods

Blood samples of sixty child with ALL at post remission induction phase as they were submitted to the Protection of Children Hospital Medical City in Baghdad, were collected. The diagnosis for ALL founded on the following findings: leukocyte count, age, involvement of tissues other than bone marrow. Patients were compared with forty healthy control who are devoid of conditions like psychiatric disorders, diabetes mellitus, or history of any drug intake are selected as control. Five ml of venous blood was drawn from sixty patients of ALL with mean age (8.34±3.33) years old, after one month induction therapy treatment and normal control. Blood samples have been collected into two vacationer tubes, one containing EDTA for measurement of blood hemoglobin (Hb), WBC count. The blood in the second part was allowed to clot for 10-15 min. at room temperature, centrifuged for (10) min. at (3000rpm). Serum was removed for measuring of biochemical parameters. Serum CD26 level was assessed at 405 nm according to the Kreisel method (Kreisel W et al., 1982). TAS and TOS of serum were determined by using automated measurement methods developed by Erel method [Erel,2004,2005]. OSI values were calculated according to the following formula (Kumari et al., 2013):

\[
OSI (A) = \frac{TOS (\text{mmol H}_2\text{O}_2 \text{Eq./L})}{TAS (\mu\text{mol Trolox Eq./L})}
\]

Myeloperoxidase (MPO) was measured by o-dianisidine as a substrate (Kumar et al., 2002). Glutathione-S-transferase (GST) was assayed using Habig WH et al method (Habig et al., 1974). Xanthine oxidoreductase activity in sera was determined as discussed by Ackermann (1974) (Ackermann, and Brill, 1974).

Statistical analyses

All statistical analyses in studies were performed using SPSS version 21.0 for Windows (Statistical Package for Social Science, Inc., USA). Expressive analysis was used to demonstrate the mean and standard deviation of variables. The significance of difference between mean values was estimated by Student T-Test. The probability p<0.05=significant, p>0.05=non-significant. Correlation analysis was used to test the linear relationship between parameters. ANOVA test was used to show the changes between variables of groups.

Results

In the current study, measurement of some clinical parameters was carried out on 60 serum specimens of children with ALL, while serum samples were collected from 40 healthy children. The host information of the studied groups is summarized in Table 1.

From the results the Hb concentration and PCV percentage in patients were found to be significantly decreased (P<0.01), when compared with that of the control, while there was a significant increase (P<0.001) in WBC count in patients when compared to control group.

Serum protein was significantly decreased (P<0.05) in patients group (6.32±1.11g/dL) compared to control group (7.54±0.56 g/dL; Table 2). Serum CD26 was observed as (85.33±0.87, and 65.48±4.22µmol/L) in patients and control respectively (Table 2). CD26 was significantly increased in patients than control (P<0.001; Table 2).

TAS in patients (1.89±0.51 mmol Trolox Eq./L) was insignificantly decreased than in control (2.17±0.39 mmol Trolox Eq./L) (P>0.05; Table 2), while TOS in patients (21.23±3.98µmol H2O2 Eq./L) was significantly increased than in control (11.33±1.57 µmol H2O2 Eq./L) (P<0.001; Table 2). OSI in patients (11.23±3.26 arbitrary unit) was significantly increased than in control (5.22±1.88) (P<0.001; Table 2).

Serum myeloperoxidase activity was observed as (105.13±34.16, and 185.44±22.12U/L) in patients and control respectively (P<0.001; Table 2). It is also clear from the result that glutathione-S-transferase activity in patients (51.32±4.33 IU/L) was significantly decreased than in control (79.99±2.79 IU/L) (P<0.001; Table 2). Xanthine oxidase activity in patients (11.73±4.02 IU/L) was significantly decreased than in control (18.76±1.32 IU/L; P<0.001; Table 2).

Table 3 showed a significant correlation between CD26 concentration and some oxidative stress parameters (enzymatic and non enzymatic) in patients with acute lymphoblastic leukemia patients at post remission induction phase. The results in Table 3, it is clear that there are negative correlation between CD26 with TAS, TOS, OSI and MPO.

myeloperoxidase activity, glutathione-S-transferase and xanthine oxidase activity (R²=0.68, 0.87, 0.78 and -0.69 respectively), while there are positive correlation with the other parameters.

Discussion

The oxidant balance in leukaemia has a benefit toward ROS production. Reactive oxygen species producing complexes have the potential for significant clinical application; either by causing direct damage to cancer cells or by inhibition of growth and existence of potential cancer cells. Reactive oxygen species (ROS) are the various group of compounds which are generated by the mature myeloid lines in an innate response. ROS have an important role in intracellular signalling process. An excessive production of ROS can lead to oxidative stress in acute and chronic leukaemia but it is unclear that ROS are involved in the initiation, progression and maintenance of diseases (Hol et al., 2011). Antioxidant enzymes interact with the free radicals in different ways, by controlling the chain of reactions. We found no significant differences in TAS values between groups of patients and control, these result in agreement with the previous studies (Rybak et al., 2012). The present result showed a significant increase in TOS and OSI, while myeloperoxidase, glutathione-s-transferase, xanthine oxidase activities showed a significant decrease in in patients with ALL at post remission induction phase comparing to control, these result agreement with other studies (Morgan et al., 1981; Battisti, 2008; El-Sabagh, 2011). Hb was found significantly decreased in ALL patients compared to control. The haemoglobin is produced by a variation of mechanisms, as well as neoplastic cell infiltration into bone marrow, also by nutritional deficiencies, and defects in erythropoietin as a result of the disease itself (Mehde et al., 2014). This finding may indicate a probable relationship between decreased Hb and decreased levels of myeloperoxidase activity and glutathione-s-transferase result to oxidative damage, agreement with the idea that effect of oxidative stress leading to cellular dysfunction and cell death (He et al., 2009). In leukaemia, the alteration in the oxidative balance plays a significant role in the growth, development and resistance to therapy.

The present study showed that serum CD26 was significantly increased in patients than control, also the result showed a significant correlation between CD26 concentration and some oxidative stress parameters (enzymatic and non enzymatic) in ALL patients. Serum CD26 levels are an important emerging marker of B-cell chronic lymphocytic leukaemia (Cro et al., 2009). Another study showed that the first treatment in B-CLL which display higher serum CD26 levels (Molica, 2009), CD26 serves as a marker of poor prognosis in T cell lymphomas CD26 (Aldinucci et al., 2004). Another study described that CD26 expression is found mainly in aggressive subtypes of non-Hodgkin’s lymphomas for example T-lymphoblastic lymphoma (LBL)/T-ALL (Carbone et al., 1995). Other work also demonstrated an enhancement in the expression of CD26 in cases of T cell acute lymphoblastic leukemia, the majority of patients with T-ALL were found to express CD26 on the tumor cell surface, with a strong correlation noted between CD26 expression and the presence of DPPIV enzyme activity in the T lymphoblasts (Klobusicka et al., 1999).

AS our knowledge no previous studied exhibited to the link between high serum CD26 levels and oxidative stress in acute and chronic leukaemia but it is unclear that ROS are involved in the initiation, progression and maintenance of diseases (Hol et al., 2011). Antioxidant enzymes interact with the free radicals in different ways, by controlling the chain of reactions. We found no significant differences in TAS values between groups of patients and control, these result in agreement with the previous studies (Rybak et al., 2012). The present result showed a significant increase in TOS and OSI, while myeloperoxidase, glutathione-s-transferase, xanthine oxidase activities showed a significant decrease in in patients with ALL at post remission induction phase comparing to control, these result agreement with other studies (Morgan et al., 1981; Battisti, 2008; El-Sabagh, 2011). Hb was found significantly decreased in ALL patients compared to control. The haemoglobin is produced by a variation of mechanisms, as well as neoplastic cell infiltration into bone marrow, also by nutritional deficiencies, and defects in erythropoietin as a result of the disease itself (Mehde et al., 2014). This finding may indicate a probable relationship between decreased Hb and decreased levels of myeloperoxidase activity and glutathione-s-transferase result to oxidative damage, agreement with the idea that effect of oxidative stress leading to cellular dysfunction and cell death (He et al., 2009). In leukaemia, the alteration in the oxidative balance plays a significant role in the growth, development and resistance to therapy.

stressed parameters (enzymatic and non enzymatic) has been established in ALL in children at post remission induction phase.

In conclusion, we demonstrated for the first time that an increase in serum CD26 is inversely associated with the myeloperoxidase activity, glutathione-s-transferase activity and xanthine oxidase activity. On the other hand the exact role of CD26 remains obscure, although our study was limited and preliminary character of findings, serum levels of CD26 might appear to be useful as a biomarker to detect oxidative stress status in ALL in children at post remission induction phase and levels of antioxidants must be regularly estimated during the treatment of child with ALL.
