

[Figure 3] Navigation Models for iPod and Mobile Phone

In addition, the operation models associated with form-image and navigation models are considered to understand the users' mental models. For example, a user generally memorizes a phone number with finger movements.

## 2-2. Target Mental Model

To predict new mental model for the combined product, the combined function-cluster in Figure 4 is developed with function-cluster models, and other target mental models such as form and interaction are sequentially developed within the context of a target mental model in Figure 4. The shared functions between products are used to make connections for cognitive consistency.

[Figure 4] Combined Function-Cluster Model (Target Mental Model for GUI Design)

## 3. Prototyping

Prototyping is a process to design new experiences based on the target mental model in Figure 4. Integrating two distinct operations, rubbing the circle of the iPod to navigate and tapping the buttons of a mobile phone to input and navigate, is a main concern for prototyping since the operations are such dominant mental models of each one. Figure 5 is a new iPhone interaction design which has a combined interface to incorporate two distinct mental models. The unique circle is for iPod users and the button layout from the old-style phone design is for mobile phone users.

## 4. Evaluation

[Figure 6] Working Prototype

The formal usability test is conducted to evaluate the prototype with four user groups. Insights from the test are that 1) users' unique habits to explore the functions for tasks are still effective, 2) the shapes of interfaces determine the users' behaviors, and 3) iPod users have distinct characters from other groups that are adaptive to accept the new. Figure 6 is a working prototype developed with Embedded Visual Basic for usability tests and Table 1 is a summary of the results.

Index		User 1	User 2	User 3	User 4
		iPod / Cell / PDA	MP3 / PDA	MP3	MP3 / Cell
Task	Making a phone call	She enters the number using key pad. If the combination of number is complex, it maybe said to her.	She cannot easily figure out how to operate.	She enters the number using menu structure instead of number things directly.	She enters the number using key pad.
	Playing Music	She easily navigates it.	She cannot navigate up and down.	She easily navigates it.	After 3 time mistake, she figure out how to navigates it.
Post-question name	Multi-Function Dial Pad	If I am not a iPod user, I may not be able to figure out the dial interface intuitively.	It is fun experience though it is a different mental model with me and the size is bigger than normal keypad.	The circle dial one is strange to her, because she never use it before.	I feel I need time to get familiar with it to reduce the mistake I might made. But I like it.
	Changeable labeled button	If it can provide more clear guide, it is good idea.	The strange things to her is why only one button is changed.	If the term of the label is described well, it is good.	I think it is good, because "enter" and "call" has a similar meaning, so it doesn't confuse me.

[Table 1] Summary of Usability Test

## 5. Conclusion

Three innovations are found through the method. The first one is integrating two function-clusters to merge two mental models. Users can extend their mental models of the products to accommodate new products. Combining two different visual interactions based on two navigation models is the second innovation. Sequential-based GUI using Focus + Context technique is design for the iPhone. The third one is merging two different types of interaction experiences. iPod uses unique interface for navigation with a circle shaped dial and that shape was also applied to the old-style phone. New physical interactions are designed for two functions, navigation and dial, together in one interface by integrating two behaviors, rubbing and tapping. However, a problem that the combined UI does not meet the mobile phone users' mental model remains as future work.

## 6. Acknowledgment

This research was in part conducted by the co-op based project for the class, Cognitive Human Factor, by Ken Douros, a manager in Human Interface Lab at Motorola.
