We present the first sky map of C IV emission line, observed with the FIMS (Far-ultraviolet IMaging Spectrograph) instrument, also known as SPEAR (the Spectroscopy of Plasma Evolution from Astrophysical Radiation), onboard the first Korean Science and Technology SATellite, STSAT-1. The emission line maps of C IV 1548, 1551A were made by fitting the spectra in each pixel with Gaussian line spread functions and a constant background. Discrete FUV sources have not been removed. The brightest source is the Vela Supernova remnant. We found many interesting diffuse features as well as many well-known sources.
