## 1. Introduction

It has been known that a uranium dioxide ( $\text{UO}_2$ ) pellet with large grains reduces the amount of fission gas released during irradiation[1], and thus the large-grained pellet is recognized as desirable at high burnup. The fabrication of large-grained  $\text{UO}_2$  pellets has been investigated so widely that many fabrication methods have been developed.

Recently, it has been known that  $\text{UO}_2$  seeds (particles) are prepared by crushing and milling defective  $\text{UO}_2$  pellets and have a beneficial effect on the grain size of  $\text{UO}_2$  pellet when they are added to  $\text{UO}_2$  powder[2]. This kind of  $\text{UO}_2$  seeds inevitably has a wide size distribution and especially has a considerable proportion of very fine sized seeds that prohibit grain growth during sintering.

This paper describes a new method of making  $\text{UO}_{2+x}$  seeds and their effects on microstructure development under conventional hydrogen sintering conditions.

## 2. Experimental Procedures

The overall experiment consists of making  $\text{UO}_{2+x}$  seeds and fabricating  $\text{UO}_2$  pellets. At first,  $\text{UO}_2$  pellets were fabricated to have a wide range of the average grain size;  $14\mu\text{m}$ ,  $8\mu\text{m}$ ,  $6\mu\text{m}$ ,  $4\mu\text{m}$ . The  $8\mu\text{m}$ -grain sized pellet was sintered at  $1700^\circ\text{C}$  for 4 h in hydrogen gas, the larger grain was at  $1900^\circ\text{C}$ , and the small grain size was at lower temperatures. These four kinds of pellets were slightly oxidized to become various  $\text{UO}_{2+x}$  seeds in the specially designed equipment shown in Fig. 1. This equipment consists of a vertical tube furnace, a perforated container, a vibrator, an air flowing tube, a receiving tube, a receiving jar.

When  $\text{UO}_2$  pellets put in the perforated container were heat treated in air, the grain boundary of  $\text{UO}_2$  pellet was predominantly attacked (oxidized) rather than the grain interior. The oxidation of  $\text{UO}_2$  to  $\text{U}_3\text{O}_8$  causes a volume expansion of about 30%, which is too large to be accommodated in the pellet. So cracks develop along the grain boundary and grain-shaped particles (seeds) can be separated from the pellet. Each separated grain-shaped particle consists of a single grain or many grains. The perforated container is designed to screen large particles, which continue to be subdivided by oxidation until grain-shaped parcels are small enough to pass the perforated container. The perforated container was vibrated to help the separated seeds to pass. The separated  $\text{UO}_{2+x}$  seeds are received in a jar set at the bottom of the furnace. The jar was kept at room temperature to prohibit further oxidation of  $\text{UO}_{2+x}$  seeds.

The four kinds of  $\text{UO}_2$  pellets, depending on the grain size, were oxidized at  $320\sim 450^\circ\text{C}$ . The produced  $\text{UO}_{2+x}$

seeds were analyzed in terms of SEM morphology, size and O/U ratio.

The  $\text{UO}_{2+x}$  seeds were added to  $\text{UO}_2$  powder and then mixed for 1h with a tumbling mixer. The powder mixtures contain the amounts of  $\text{UO}_{2+x}$  seeds ranging from 2wt% to 8wt%. The powder mixture was pressed under 300 MPa to form a green pellet and then sintered at  $1700^\circ\text{C}$  for 4h in hydrogen gas. The  $\text{UO}_2$  pellet was examined in terms of grain size. In order to examine the resintering behavior, the  $\text{UO}_2$  pellet was heat-treated at  $1700^\circ\text{C}$  for 24h in  $\text{Ar-H}_2$  gas.

## 3. Results and Discussion

The  $\text{UO}_{2+x}$  seeds prepared from the four kinds of  $\text{UO}_2$  pellets are shown in Fig. 2. The polyhedral shape of  $\text{UO}_{2+x}$  seeds is identical to that of the grain. The sizes of  $\text{UO}_{2+x}$  seeds are also similar to the grain size of pre-oxidized  $\text{UO}_2$  pellets, so the size of a seed is mainly determined by the grain size of the pre-oxidized  $\text{UO}_2$  pellets. However, it is found that part of the  $\text{UO}_{2+x}$  seeds is composed of multi-grains. These multi-grained seeds seem to be easily formed as the grain size of the pre-oxidized  $\text{UO}_2$  pellet decreases. This is probably ascribed to the fact that a small-grained pellet, which includes such a large area of the grain boundary, needs much more energy in separating all grain boundaries than a large-grained pellet.

The oxygen to uranium ratio of  $\text{UO}_{2+x}$  seeds was assessed from the weight gain occurring by the oxidation of the  $\text{UO}_{2+x}$  seed to  $\text{U}_3\text{O}_8$ . The values are in the range between 2.2 and 2.3, and they tend to become larger as the size of seeds decreases. In addition, the SEM morphology reveals some

fine cracks on the surface, which developed by the  $\text{U}_3\text{O}_8$  formation. So it is believed that the surface of the  $\text{UO}_{2+x}$  seed contains  $\text{U}_3\text{O}_8$  phase and the interior contains  $\text{UO}_{2+x}$  phase.

The  $\text{UO}_{2+x}$  seeds were added to  $\text{UO}_2$  powder and then  $\text{UO}_2$  pellets were fabricated through the conventional sintering process. The pellet microstructure is shown in Fig. 3. Large grains are mainly formed, with some regions of small grains. The size of large grains increases with the size of the added  $\text{UO}_{2+x}$  seeds. The average grain size determined by the linear intercept method is  $14\mu\text{m}$  when the 5wt% of  $6\mu\text{m}$ -seeds is added to  $\text{UO}_2$  powder.

The results of the resintering test indicate that the seeded  $\text{UO}_2$  pellet with large grains is thermally more stable than the normal  $\text{UO}_2$  pellet.

#### 4. Conclusion

The grain-shaped  $\text{UO}_{2+x}$  seeds are fabricated by oxidizing the grain boundary of  $\text{UO}_2$  pellets. This developed technique uses a perforated container that can detach the separated  $\text{UO}_{2+x}$  seeds from the oxidizing  $\text{UO}_2$  pellet. The size of the  $\text{UO}_{2+x}$  seeds is quite dependent on the grain size of pre-oxidized  $\text{UO}_2$  pellet, so the control of seed size can be easily achieved by varying the grain size of pre-oxidized  $\text{UO}_2$  pellet.

The  $\text{UO}_2$  pellet fabricated by adding the  $\text{UO}_{2+x}$  seeds has the grain structure in which large grains are mainly formed with some regions of small grains. The average grain size of  $\text{UO}_2$  pellet is about  $14\mu\text{m}$ , and the seeded  $\text{UO}_2$  pellet is

thermally more stable than the normal (small-grained)  $\text{UO}_2$  pellet.
