${ }^{\text {a }}$ The reaction was carried out with equimolar amounts of an amino acid, the reagent, and triethylamine. ${ }^{\delta}$ Method A: in aqueous DMF at room temperature. Method B: in p-dioxane at $80^{\circ} \mathrm{C} .{ }^{\circ}$ Isolated yields.
though the reaction required 10 h at $80^{\circ} \mathrm{C}$ for completion of the reaction. Under the present conditions, several amino acids were cleanly converted into the corresponding N -Boc amino acids as shown in Table 2. However, benzyloxycarbonylation of amino acids occurred cleanly and rapidly in aqueous $\mathrm{N}, \mathrm{N}$ ' -dimethylformamide and the reaction was generally complete 10 min at room temperature. The identities of $\mathrm{N}-\mathrm{Boc}$ and $\mathrm{N}-\mathrm{Cb} z$ amino acids were confirmed by comparison NMR, mp, and $[\alpha]_{D}$ values with reported data.

# A Simple Approach to the Valerane Skeleton 

Jong-Gab Jun ${ }^{\text {* }}$<br>Department of Chemistry, Hallym University, Chunchon 200

Bradford P. Mundy

Department of Chemistry, Montana State University, Bozeman, MT 59717, U.S.A. Received August 21, 1987

The carbon framework of the valerane sesquiterpenes provides stereochemically interesting cis-dimethyl substitution around the ring junction. ${ }^{1}$ The parent compound is obtained by the reduction of 1 -valeranone which isolated from Vateriana officinalis. ${ }^{2}$ As a continuation of our studies using dianion methodology ${ }^{3}$ we explored the stereospecific formation of the parent, valerane, (1).

Our approach is different from that recently reported by Garratt ${ }^{4}$ in the timing of incorporation of the isopropyl group. Hydrogenolysis of the C-S bond of 12 -thia[4.4.3]propell-3-

ene(2) by using Raney-nickel whose synthesis was reported in the previous article ${ }^{5}$, provided the required $c i s-9,10$-dimethyl decalin-2-ene-(3) in $73 \%$ yield. The introduction of the isopropyl group was achieved according to the sequences shown in Figure 1. Hydroboration of the alkene bond of 3

Flgure 1. The synthesis of valerane.

Figure 2. Conformational assignment for valerane.
gave the alcohol 4 in $95 \%$ yield. Oxidation of 4 with PDC in methylene chloride for 24 hours gave the corresponding ketone(5) in $93 \%$ conversion. Treatment of 5 with isopropylmagnesium chloride in ether gave an epimeric mixture of alcohol 6 in $88 \%$ yield. Dehydration of 6 with phosphorous oxychloride in pyridine at $90^{\circ} \mathrm{C}$ gave a $73 \%$ yield of a $45: 55$ mixture of 7a and $\mathbf{7 b}$ respectively. Catalytic reduction of these olefinic mixture by using hydrogenator at 60 psi for 12 hours with palladium on carbon in hexane gave a $45: 55 \mathrm{mix}-$ ture of the isomeric valeranes in $80 \%$ yield.

Rao ${ }^{6}$ and Baldwin ${ }^{7}$ synthesized 1 and 8 as a 40:60 ratio and the reported spectral data is identical with ours. ${ }^{B}$. In view of the flexible nature of the cis decalin, valerane could exist in at least two interchangeable all-chair conformations such as the steroid cis conformation or the nonsteroid cis conformation (Figure 2). Hartshorn ${ }^{9}$ and Hikino ${ }^{10}$ proved that valeranon exists in the steroid cis conformation from a study of its optical rotatory dispersion. Also, we proved the conformation of 1 and 8 by a NOE experiment as follows: Irradition of the 0.83 ppm resonance in 1 gave a positive NOE effect at 1.51 ppm , but irradition of 0.84 and 0.79 ppm in 8 did not give any positive NOE effect, which indicates 1 is in the steroid cis conformation and 8 is in the nonsteroid cis conformation.
