## ON OSCILLATIONS OF SECOND ORDER LINEAR DIFFERENTIAL EQUATIONS

## A. Zaghrout

The second order differential equations of the form $\left(p y^{\prime}\right)^{\prime}+q y=f$ are investigated. Sufficient conditions to ensure boundedness and oscillations of solutions are given.

## I. Introduction

Consider the self-adjoint second order linear differential equation

$$
\begin{equation*}
\left[p(x) y^{\prime}(x)\right]^{\prime}+q(x) y(x)=0 \tag{H}
\end{equation*}
$$

and the corresponding nonhomogeneous equation

$$
\begin{equation*}
\left[p(x) y^{\prime}(x)\right]^{\prime}+q(x) y(x)=f(x) . \tag{NH}
\end{equation*}
$$

The functions $p, q$ and $f$ are positive continuous functions on an interval $I=[a, \infty), a \geq 0$ and their products are nondecreasing, unbounded, and of class $C^{\prime}[I]$.

It is well known that if

$$
\begin{equation*}
\int_{0}^{\infty}[1 / p(x)] d x=\infty, \quad \int_{0}^{\infty} q(x) d x=\infty \tag{1.1}
\end{equation*}
$$

then every solution $y(x)$ of (H) oscillates on $I$.
In recent papers Maki [8], Komkov [5] showed out the usefulness of the transformation $y(x)=w(x) z(x)$ in studying qualitative properties of $(\mathrm{H})$. This transformation transforms

$$
\begin{equation*}
y^{\prime \prime}+q(x) y=f(x) \tag{0.1}
\end{equation*}
$$

Received March 20, 1990.
into

$$
\begin{equation*}
\left(w^{2} z^{\prime}\right)^{\prime}+w\left(w^{\prime \prime}+q w\right) z=f w \tag{0.2}
\end{equation*}
$$

If $w(t)$ is a solution of

$$
\begin{equation*}
w^{\prime \prime}+q w=0 \tag{0.3}
\end{equation*}
$$

then ( 0.2 ) becomes

$$
\begin{equation*}
\left(w^{2} z^{\prime}\right)^{\prime}=f w \tag{0.4}
\end{equation*}
$$

Equation (0.4) enables us to study the oscillatory behaviour of solutions of ( 0.1 ) in terms of the forcing function $f$ and the nonoscillatory solutions of (0.3).

Fink and Mary [4] proved that if the equation (H) is oscillaroty then the equation

$$
\left(p(x) z^{\prime}(x)\right)^{\prime}+\lambda q(x) z(x)=0
$$

is also oscillatory for $\lambda>1$. It is clear that this equation can be written as

$$
\left(p(x) z^{\prime}(x) / \lambda\right)^{\prime}+q(x) z(x)=0
$$

Also Erbe [2], proved that multiplying the coefficient $q(x)$ by a function $a(x)$ preserves the oscillatory property. The purpose of this paper is to eatablish sufficient conditions to ensure boundedness, and oscillations of solutions of $(\mathrm{H})$ and (NH). We shall make use of the following notions for every solution $y(x)$ of (H).

$$
\begin{gather*}
{\left[(p q)^{\prime}\right]^{+}=\left\{\left|(p q)^{\prime}\right|+(p q)^{\prime}\right\} / 2 \quad\left[(p q)^{\prime}\right]^{-}=\left\{\left|(p q)^{\prime}\right|-(p q)^{\prime}\right\} / 2}  \tag{1.2}\\
M\left[y, y^{\prime}\right]=y^{2}+\left\{\left(p y^{\prime}\right)^{2} / p q\right\} \tag{1.3}
\end{gather*}
$$

with $M_{a}=M\left[y(a), y^{\prime}(a)\right]>0$. Also the following theorem and definition will be used in our analysis:

Theorem A [3]. If
(i) $p(x)>k>0$ on $I$ and $\int_{0}^{\infty}(1 / p(x)) d x=\infty$,
(ii) $q(x)>k>0$,
(iii) $f(x) \in L(0, \infty)$,
then all nonoscillatory solutions $y(x)$ of (NH) satisfy $\lim _{x \rightarrow \infty} y(x)=0$.

Definition 1. Equation (H) is said to be disconjugate on $I$ if no nontrivial solution of it has more than one zero.

Let $C[a, b]$ denote the set of absolutely continuous functions $r(x)$ such that $r(a)=r(b)=0$ and $\left|r^{\prime}(x)\right| \in L$. Let

$$
\begin{equation*}
H[r ; a, b]=\int_{a}^{b}\left(p\left(r^{\prime}\right)^{2}-q r^{2}\right) d x \tag{1.4}
\end{equation*}
$$

for all $r \in C[a, b]$. It well known, [1], that (H) is disconjugate on $|a, b|$ if and only if $J|r, a, b|>0$ for all admissible functions $r(x),(r(x) \not \equiv 0)$.

## 2. Main Results:

First we will establish the following theorem:

## Theorem 2.1.

$$
\begin{equation*}
\lim _{x \rightarrow \infty} \int_{a}^{x}\left\{\left[(p g)^{\prime}\right]^{\prime} / p q\right\} d t \tag{2.1}
\end{equation*}
$$

exists and is finite, then for any solution $y(x)$ of $(H)$

$$
\begin{equation*}
\lim _{x \rightarrow \infty} \int_{a}^{x}\left\{(p q)^{\prime}\left(p y^{\prime}\right)^{2} / p q\right\} d t \tag{2.2}
\end{equation*}
$$

exists and is finite, and all solutions $y(x)$ remain bounded.
Proof. Differentiating (1.3) and using (H) we obtain

$$
\begin{equation*}
\left(M\left[y, y^{\prime}\right]\right)^{\prime}=-(p q)^{\prime}\left(p y^{\prime}\right)^{2} /(p q)^{2} . \tag{2.3}
\end{equation*}
$$

Hence

$$
\begin{equation*}
M\left[y, y^{\prime}\right]=M_{a}-\int_{a}^{x}(p q)^{\prime}\left(p y^{\prime}\right)^{2} /(p q)^{2} d t \tag{2.4}
\end{equation*}
$$

Then we shall show that the expression (2.4) exists and is finite. Using (1.2), (1.3), (2.3) and (2.4) we have

$$
\begin{align*}
0 & \leq\left(p y^{\prime}\right)^{2} / p q \leq\left\{\left(p y^{\prime}\right)^{2} / p q\right\}+y^{2}=M\left[y, y^{\prime}\right] \\
& =M_{a}-\int_{a}^{x}(p q)^{\prime}\left(p y^{\prime}\right)^{2} /(p q)^{2} d t \\
& =M_{a}-\int_{a}^{x}\left[\left\{(p q)^{\prime}\left(p y^{\prime}\right)^{2}\right\}^{+}+\left\{(p q)^{\prime}\left(p y^{\prime}\right)^{2}\right\}^{-}\right] /(p q)^{2} d t \tag{2.5}
\end{align*}
$$

Hence

$$
\begin{equation*}
\left(p y^{\prime}\right)^{2} / p q \leq M_{a}+\int_{a}^{x}\left\{\left(p y^{\prime}\right)^{2}(p q)^{\prime}\right\}^{-} /(p q)^{2} d t \tag{2.6}
\end{equation*}
$$

and

$$
\begin{equation*}
\int_{a}^{x}\left\{(p q)^{\prime}\left(p y^{\prime}\right)^{2}\right\}^{+} /(p q)^{2} d t \leq M_{a}+\int_{a}^{x}\left\{(p q)^{\prime}\left(p y^{\prime}\right)^{2}\right\}^{-} /(p q)^{2} d t \tag{2.7}
\end{equation*}
$$

From (2.6) and by using Gronwall inequality we have

$$
\begin{aligned}
\left(p y^{\prime}\right)^{2} / p q & \leq M_{a} \exp \left(\int_{a}^{x}\left\{(p q)^{\prime}\right\}^{-} / p q d t\right) \\
& \leq M_{a} \exp \left(\int_{a}^{\infty}\left\{(p q)^{\prime}\right\}^{-} / p q d t\right)
\end{aligned}
$$

and thus $\left(p y^{\prime}\right)^{2} / p q$ is bounded on $I$. It can be easily seen, from (2.7), that

$$
\begin{aligned}
& \lim _{x \rightarrow \infty} \int_{a}^{x}\left\{(p q)^{\prime}\left(p y^{\prime}\right)^{2}\right\}^{-} /(p q)^{2} d t \\
& \lim _{x \rightarrow \infty} \int_{a}^{x}\left\{(p q)^{\prime}\left(p y^{\prime}\right)^{2}\right\}^{+} /(p q)^{2} d t
\end{aligned}
$$

exist and are finite and the result follows from (2.2) and (2.5).
Theorem 2.2. If

$$
\begin{align*}
& \text { (i) } \int_{a}^{\infty}(1 / p) d x=\infty, \int_{a}^{\infty} q d x=\infty, \lim _{x \rightarrow \infty} p / q=0,  \tag{2.8}\\
& \text { (ii) } \lim _{x \rightarrow \infty} \int_{a}^{x}\left\{(p q)^{\prime} / p q\right\} d t, \tag{2.9}
\end{align*}
$$

exists and finite, then all solutions of $(H)$ are bounded and oscilatory on $I$.

Proof. Theorem 2.1 implies that the solutions of $(\mathrm{H})$ are bounded on $I$ and $M\left[y, y^{\prime}\right]$ remains bounded on $I$. By Leighton result [6] and (1.1), it follows that under conditions (2.8) and (2.9), all solutions of (H) are oscillatory. This completes the proof.

Theorem 2.3. A necessary and sufficient condition for solutions of $(H)$ to be oscillatory is that there exists a function $w(x) \neq 0$ of class $C^{\prime}[I]$ for which

$$
\begin{equation*}
\int_{a}^{\infty}(1 / p w) d x=\infty, \int_{a}^{\infty} w\left[\left(p w^{\prime}\right)^{\prime}+q w\right] d x=\infty \tag{2.10}
\end{equation*}
$$

hold.
Proof. Let $u(x)$ and $v(x)$ be any two linearly independent solution of (H) for which Abel's formula is given by

$$
p W=p\left[u v^{\prime}-u^{\prime} v\right]=k
$$

where $W$ is the Wronskian of $u$ and $v$, and $k>0$ is a constant. It is clear that

$$
\begin{equation*}
w(x)=\sqrt{u^{2}(x)+v^{2}(x)} \tag{2.11}
\end{equation*}
$$

is a solution of

$$
\begin{equation*}
p w^{3}\left[\left(p w^{\prime}\right)^{\prime}+q w\right]=k^{2} \tag{2.12}
\end{equation*}
$$

The transformation $y=w z$ transforms (H) into

$$
\begin{equation*}
\left(p w^{2} z^{\prime}\right)^{\prime}+w\left[\left(p w^{\prime}\right)^{\prime}+q w\right] z=0 \tag{2.13}
\end{equation*}
$$

Further, if $w(x)$ is such that

$$
\begin{equation*}
\left(p w^{2}\right) w\left[\left(p w^{\prime}\right)^{\prime}+q w\right]=1 \tag{2.14}
\end{equation*}
$$

and using the transformation

$$
t=\int_{a}^{x}\left[1 /\left(r(t) u^{2}(t)\right)\right] d t
$$

of the independent variable, then the, two linearly independent solutions of (2.13) are

$$
\sin \int_{a}^{x}\left[1 / r(t) u^{2}(t)\right] d t, \cos \int_{a}^{x}\left[1 / r(t) u^{2}(t)\right] d t
$$

But (2.14) is simply (12.12) with $k=1$, thus solutions of (H) are oscillatory if and only if solutions of (2.13) are oscillatory there. It follows that if solutions of $(\mathrm{H})$ are oscillatory on $I$, then there exists a function $w(x) \neq 0$ of class $C^{\prime}[1]$ such that conditions (2.10) hold.

Conversely, if there exists function $w(x) \neq 0$ of class $C^{\prime}[I]$ such the condition (2.10) hold, then by condition (1.1) and Theorem (2.2), solutions of $(\mathrm{H})$ are oscillatory.

As a consequence result for equation (2.13) is following:
Theorem 2.4. If there exists a function $w(x)>0$ of class $C^{2}[I]$ such that $\left(p w^{\prime}\right)^{\prime}+q w<0$ for large $x$, then the solutions of $(H)$ are nonoscillatory on $I$.

Example 1. By taking $p(x)=1, a=1$, then equation (H) is reduced to the form

$$
y^{\prime \prime}+q(x) y=0,1 \leq x<\infty
$$

and conditions (2.10) become

$$
\int_{1}^{\infty}\left(1 / w^{2}\right) d x=\infty, \int_{1}^{\infty} w\left(w^{2}+q w\right) d x=\infty .
$$

By setting $w=x^{\frac{1}{2}}$, then these conditions are reduced to

$$
\int_{1}^{\infty}(1 / x) d x=\infty, \int_{1}^{\infty}\{x q+|1 / 4 x|\} d x=\infty
$$

then the solutions of $y^{\prime \prime}+q(x) y=0$ are oscillatory on $[1, \infty)$.
Example 2. Consider the differential equations

$$
y^{\prime \prime}+\left(k / x^{3}\right) y=0,1 \leq x<\infty
$$

and there exists a function $z$ such that

$$
\begin{equation*}
z\left(x^{\prime \prime}+\left(k / x^{3}\right) z\right)<0, \text { for large } x . \tag{2.15}
\end{equation*}
$$

By a choice $z=x^{\frac{1}{2}}$, then the solutions of (2.15) are nonoscillatory on $[1, \infty)$.
Theorem 2.5. If

$$
\begin{equation*}
\int_{1}^{\infty}(p q)^{\prime} / p q d x<\infty, \int_{1}^{\infty} f /(p q)^{\frac{1}{2}} d x<\infty \tag{2.16}
\end{equation*}
$$

then all solutions of $(\mathrm{NH})$ are bounded.
Proof. Using the substitution $w=y^{\prime}$, then the equation (NH) takes the form

$$
w^{\prime}=\left(-p^{\prime} w-q y+f\right) / p
$$

Define

$$
E(y, w, x)=\left[p w^{2} / 2 q\right]+x^{2} / 2 .
$$

Then

$$
\begin{aligned}
\frac{d E}{d x} & =(f w / q)-\left(w^{2}(p q)^{\prime} / 2 q^{2}\right) \\
& \leq(f w / q)+\left\{(p q)^{\prime} / p q\right\} E
\end{aligned}
$$

But since

$$
|f w / q| \leq\left(f /(p q)^{\frac{1}{2}}\right) \cdot\left\{\left(p w^{2} / 2 q\right)+\frac{1}{2}\right\}
$$

then

$$
E^{\prime}=\left[f /(p q)^{\frac{1}{2}}+(p q)^{\prime} / p q\right] E+f / 2(p q)^{\frac{1}{2}}
$$

Using condition (2.15) and Gronwall's inequality it follows that $E$ is bounded, and consequently $y(x)$ is bounded. This completes the proof.

Theorem 2.6. If there exists a positive function $w(x)$ such that $w(x) f(x) \in$ $L(I), w\left(w^{\prime \prime}+q w\right)>k_{1} w^{2}>k_{1}$ for some $k_{1}>0$ and $\int_{1}^{\infty}\left(1 / w^{2}\right) d x=\infty$, then every nonoscillatory solution of $(N H)$ with $p(t)=1$ satisfies

$$
\lim _{x \rightarrow \infty} y(x) w(x)=0
$$

Proof. The result follows from Theorem A and the hypothesis, each nonoscillatory solutions of (0.2) satisfies $\lim _{x \rightarrow \infty} z(x)=0$.

Theorem 2.7. If $(N H)$ has a solution $r(x)<0$ on $I$, then equation ( $H$ ) is disconjugate.
Proof. It is sufficient to show that, for any number $c>a$, equation (H) is disconjugate on $[a, c] \in I$ (i.e. $J[r, a, c]>0$ for all $r \in C[a, b], r(x) \not \equiv 0)$. Let

$$
w=\left(p r^{\prime} / r\right)
$$

then

$$
\begin{aligned}
w^{\prime} & =\left[\left(p r^{\prime}\right)^{\prime} r-p\left(r^{\prime}\right)^{2}\right] / r^{2}=f / r-q-\left[\left(p r^{\prime}\right)^{2} / r^{2}\right] / p \\
& =(f / r)-q-\left(w^{2} / p\right)
\end{aligned}
$$

Hence

$$
-q=w^{\prime}-\left(w^{2} / p\right)-(f / r) .
$$

Therefore for any $z \in C[a, c]$ we have

$$
-q z^{2}=w^{\prime} z^{2}+\left(w^{2} z^{2} / p\right)-\left(f z^{2} / r\right)
$$

Using (1.4) we have

$$
\begin{aligned}
H[z ; a, c] & =\int_{a}^{c}\left(p\left(z^{\prime}\right)^{2}-q z^{2}\right) d x \\
& \left.=\int_{a}^{c}\left\{w^{\prime} z^{2}+p\left(z^{\prime}\right)^{2}+\left(w^{2} z^{2} / p\right)-f z^{2} / r\right)\right\} d x \\
& \left.=w z^{2}\right]_{a}^{c}-\int_{a}^{c} 2 w z z^{\prime} d x+\int_{a}^{c}\left\{p\left(z^{\prime}\right)^{2}+\left(w^{2} z^{2} / p\right)-\left(f z^{2} / r\right)\right\} d x \\
& =\int_{a}^{c}\left\{p\left(z^{\prime}\right)^{2}+\left(w^{2} z^{2} / p\right)-2 w z z^{\prime}-\left(f z^{2} / r\right)\right\} d x \\
& =\int_{a}^{c}\left\{\left(p^{\frac{1}{2}} z^{\prime}-p^{-\frac{1}{2}} w z\right)^{2}-f z^{2} / r\right\} d x>0 .
\end{aligned}
$$

This completes the proof.
