
a brown solution was obtained. After stripping off the solvent, 100 mL of ethylether was added to dissolve the reaction residue. After being washed with water, the etheral solution was concentrated and developed with benzene/diethyl ether (19/1) solvent on TLC. The products ( $R_{f}=0.2$ ), phenanthridine ( $12,178 \mathrm{mg}, 31 \%$ yield, $\mathrm{mp} .105-106^{\circ} \mathrm{C}$, lit $\mathrm{mp} .106-107$ $\left.{ }^{\circ} \mathrm{C}\right)^{6}$ and $5,5^{\prime}, 6,6^{\prime}$-tetrahydro-6,6'-biphenanthridyl $\left(R_{f}=0.8,11\right.$, $30 \mathrm{mg} .5 \%, \mathrm{mp} .176-183^{\circ} \mathrm{C}$, lit. $\left.175-185^{\circ} \mathrm{C}\right)^{7}$ was obtained. The photochemical reaction of N -benzyl-2-iodoaniline (13) gave phenanthridine (12) ( $128 \mathrm{mg}, 22 \%$ ) and 2-benzylaniline (14) ( $96 \mathrm{mg}, 16 \%$ ) under the above photochemical reaction condition of 10. The latter probably came from secondary PhotoFries type reaction of photoreduction product $N$-benzylaniline. We are studying the mechanistic pathway of the photocyclization reactions.

## Catalytic Hydroacylation of Aldehyde with $\alpha, \omega$ dienes by $\mathbf{R h}(\mathrm{I})$ and Isomerization of the Terminal olefin to the Internal olefin

## Chul-Ho Jun* and Jung-Bu Kang

Agency of Defense Development, Yuseong P.O. Box 35, Taejon 305-600

Received September 1, 1992

C-H bond activation by transition metals is one of current interests in organometallic chemistry ${ }^{1}$. Especially aldehydic C-H bond cleavage and its application to organic synthesis of ketones through hydroacylation have been studied ${ }^{2}$. One of the major limitation for this process is decarbonylation ${ }^{3}$. To solve this problem, aldimines were applied for the synthesis of ketimines, the precursor of ketones, through C-H bond cleavage of the aldimines with $\mathrm{C}=\mathrm{N}$ bond instead of $\mathrm{C}=\mathrm{O}$ bond, using picoline system which can be used for good cyclometallation tool and can be easily removed by hydrolysis after the reaction ${ }^{4}$. Another good cyclometallation tool is a 8 -quinolinyl system which does not show any decarbonylation, since they form the stable 5 -membered ring metallacyclic complexes ${ }^{5}$. As a model study for hydrometallation through $\mathrm{C} \cdot \mathrm{H}$ bond activation, it has been applied to many different reactions such as $\mathrm{C}-\mathrm{C}$ bond cleavage of the strained ring molecule ${ }^{6}$, synthesis of $\beta, \gamma$-unsaturated ketones ${ }^{7}$, and to the elucidation of olefin isomerization mechanism ${ }^{8}$. In this paper we report the catalytic hydroacylation of aldehyde and isomerization of olefin by $\mathrm{Rh}(\mathrm{I})$ with a, $\omega$-dienes.

## Results and Discussion

"Internal olefinic derivatives are mixtures of cis- and trans-isimers, detected by GC/MS, which are inseparable by column chromatography. ${ }^{\text {Determined by }}$ 'H-NMR spectra. 'Isolated by coJumn chromatography.

Scheme 1.
were purified by column-chromatography to give 8 -quinolinyl hex-4-enyl ketone (3) and 8-quinolinyl hex-5enyl ketone (4) in a $92: 8$ ratio in $47 \%$ yield (Table 1). Any other internal olefinic derivative has not been obtained. The mechanism for the formation of the compounds 3 and 4 can be deduced as shown in Scheme 1. The first step of this catalytic reaction must be aldehydic $\mathrm{C}-\mathrm{H}$ bond cleavage in 1 by $\mathrm{Rh}(\mathrm{I})$ of 2 to generate the acylrhodium(III) hydride 5, already isolated and characterized by the stoichiometric reaction ${ }^{5}$. Subsequent 1,5 -hexadiene exchange with the coordinated triphenylphosphine in 5 give 6. At this stage there are two ways of the hydride insertions into coordinated 1,5 -hexadiene in 6 : One is to follow the Markownikoff's rule, and the other the anti: larkownikoff's rule. According to the Markownikoff's rule, the hydride migrates to the C-1 of 1,5 -hexadiene in 6 to form the $2^{\circ}$ alkenyl rhodium(III) complex 7 , followed by $\beta$ elimination of the hex-5-en-2-yl group in 7 to give 8 as a transient intermediate. The hydride insertion into the C-2 of 1 ,4-hexadiene in 8 generates the acylrhodium(III) hex-4enyl complex 9. Reductive-elimination of the resulting comp-

13

$\mid \mathrm{H}$-insertion

12
Scheme 2.
lex 9 produces 3 with regeneration of the catalyst 2. However, according to the anti-Markownikoff's rule, the hydride migrates to the C - 2 of the coordinated 1,5 -hexadiene in 6 affords the acylrhodium(III) hex-5-enyl complex 10. Reduc-tive-elimination from 10 produces 4. Considering the product ratio of $92: 8$ for 3 and 4, the major olefin-insertion pathway must be 6 to 7 rather than 6 to 10 despite the fact that the $1^{\circ}$ alkyl metal complex is must more stable than the $2^{\circ}$ alkyl metal complex ${ }^{9}$. The reason must be the formation of the stable metallacyclic complex in 7 compared with that in 10. Considering that there are many known 5 -membered ring metallacyclic complexes which are supposed to be the most stable size, it can be concluded that organometallic complexes have tendencies to form the 5 -membered ring metallacycle ${ }^{10}$.
To test the formation of the intermediate 7, stoichiometric reaction was applied as shown in Scheme 2. Compound 1 reacted with ( 1,5 -hexadiene)rhodium(I) chloride dimer (11) in ether at r.t. for 10 min to give yellow precipitate which was supposed to be 12 through the formation of the intermediate 6. To the complex 12 was added pyridine to retard the ole-fin-isomerization, since the metallacyclic $\omega$-alkenyl complex has tendencies to transform into the $\pi$-alkyl complexes without coordinating ligand ${ }^{8}$. After an additional stirring for 15 h , ligand-promoted reductive-elimination from the resulting complex 13 by trimethylphosphite gave 8-quinolinyl hex-5-en-2-yl ketone (14) in $97 \%$ yield after chromatographic isolation. From the result of obtaining 14 as a final product, the formation of the complex 12 can be easily inferred, explaining that the hydride in 6 migrates to the $\mathrm{C}-1$ of $\mathbf{i}, 5$-hexadiene by the Markownikoff's rule to make the stable 5.5membered ring metallacyclic complex.

To correlate the stability of the metallacycles, formed from $\alpha, \omega$-dienes, with the product distribution, various $\alpha, \omega$-dienes were applied to the catalytic reactions under the identical reaction conditions. The final results are also shown in Table 1. With 1,4 -pentadiene, the product ratio of 8 -quinolinyl pent-4-enyl ketone and 8 -quinolinyl pent-3-enyl ketone is $67: 33$, in which the major pathway follows the anti-Markownikoff's rule (entry No. 1). It explains that the 5.5 -membered metallacyclic omplex like 16a is more stable than the smaller ringsized 4.5 -membered ring metallacyclic complex like $15 a$ as an intermediate. However in the case of long chain $\alpha,(\omega)$-diene

15a $n=1$
15b $n=3$
$15 \mathrm{c} n=4$

16a $n=1$
16b $n=3$
16c $n=4$
such as 1,6 -heptadiene and 1,7 -octadiene, each reaction resulted in 8 -quinolinyl hept-5-enyl ketone and 8-quinolinyl oct-6-enyl ketone exclusively (entries 3 and 4). On the contrary to the reaction of 1,4 -pentadiene, those of 1,6 -heptadiene and 1,7 -octadiene follows the Markownikoff's rule to make the small ring as possible as it can, since they should form 15b and 15 c rather than 16 b and 16 c to stabilize the intermediates.

## Conclusion

From the above results, it is possible to synthesize different alkenyl ketones from aldehyds with $\alpha$, $\omega$-dienes by hydroacylation. Depending on the ring-size of the intermediate. internal olefinic ketone or terminal olefinic ketone has been obtained. In the case of 1,4 -pentadiene, major product is pent-4-enyl ketone while in $\alpha, \omega$-diene, longer than 1,4 -pentadiene such as 1,6 -heptadiene and 1,7 -octadiene, the major product consists of alkenyl ketones having an internal olefin group. Further hydroacylation of aldehyde and the olefin isomerization mechanism is under study.

## Experimental

Compound I was prepared by the published procedure ${ }^{11}$. Wilkinson's complex, (1,5-hexdiene) rhodium(I) chloride diemer, 1,4 -pentadiene, 1,5 -hexadiene, 1,6 -heptadiene and 1,7 octadiene were purchased from Aldrich Chemical Co., and used without further purification. Solvents were distilled and stored over molecular sieves ( $4 \AA$ ). NMR spectra were recorded with a Brucker $\mathrm{AC}-200$ ( 200 MHz ) spectrometer. The chemical shifts ( $\delta$ ) are in ppm relative to internal $\mathrm{Me}_{4} \mathrm{Si}$. Infrared spectra were recorded with a Perkin-Elmer 683 spectrometer. Mass spectra were obtained on Hewlett-Packard HP 5971A mass spectrometer equipped with a HP 5890 series II Gas Chromatograph. Column-Chromatography was performed on Merck Silica Gel 60.

## General Procedure

Catalytic Reaction of 1 and $\alpha, \omega$-Diene. A scew-capped pressure vial was charged with Wilkinson's complex (2) $\left(6.2 \times 10^{-2} \mathrm{mmol}\right)$ dissolved in toluene ( $1 \mathrm{~m} /$ ) and the solution flushed with nitogen, and 8-quinotinecarboxatdehyde (1) (6.3 $\times 10^{-1} \mathrm{mmol}$ ) added. After stirring for 5 min at room temperature, $\alpha, \omega$-diene ( 6.1 mmol ) was added. After the reaction vial was kept at $130^{\circ} \mathrm{C}$ for 6 h , with stirring, the products were separated and purified by column-chromatography with hexane and ethylacetate ( $5: 2$ ) as an eluent. The product ratio was determined by ${ }^{1} \mathrm{H}$-NMR spectra, comparing the integrations of the terminal olefinic ( $=\mathrm{CH}_{2}$ ) peaks at 4.8-5.1
ppm and the internal olefinic ( $-\mathrm{CH}=\mathrm{CH}$ ) peaks at 5.4 ppm in the product mixture.

Stolchiometric Reaction of 1 and (1,5-Hexadiene) Rhodium(l) Chloride Dimer(11). A dry Schlenk vessel was charged with $1\left(1.9 \times 10^{-1} \mathrm{mmol}\right)$ dissolved in THF ( 0.05 $\mathrm{ml})$, flushed with nitrogen, and $11\left(0.9 \times 10^{-2} \mathrm{mmol}\right.$ ) added. After 5 min stirring at room temperature, pyridine ( $1 \mathrm{~m} /$ ) was added. The mixture was kept at room temperature for 15 h , and trimethylphosphite ( 0.5 ml ) was added and stirred for additional 1 h . The resulting mixture was reduced in volume and the product separated by column-chromatography with hexane and ethylacetate ( $5: 2$ ) to give pure 14 in $97 \%$ yield. 14: ${ }^{1} \mathrm{H}-\mathrm{NMR}\left(200 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta(\mathrm{ppm}) 8.92$ (dd, $J=4.2 \& 1.9 \mathrm{~Hz}, \mathrm{H}$ of. $\mathrm{C}-2$ in quinoline), $8.2-7.3$ ( $\mathrm{m}, 5 \mathrm{H}$, of quinoline), $5.8(\mathrm{~m}, 1 \mathrm{H},-\mathrm{CH}=$ ), 5.01-4.86 (ABX system, 2 H , $=\mathrm{CH}_{2}$ ), 3.85 (hexet, $J=6 \mathrm{~Hz}, 1 \mathrm{H}, \alpha-\mathrm{CH}$ to CO$), 2.13(\mathrm{~m}, 2 \mathrm{H}$, $-\mathrm{CH}_{2}-\mathrm{C}=$ ), $1.96\left(\mathrm{~m}, 1 \mathrm{H}\right.$, one of diastereotopic H in $\beta-\mathrm{CH}_{2}$ to CO ), 1.52 (m, 1 H , another diastereotopic H in $\beta-\mathrm{CH}_{2}$ to CO ), 1.24 ( $\mathrm{d}, J=6.9 \mathrm{~Hz}, 3 \mathrm{H}, \mathrm{CH}_{3}$ ); IR (neat) $1685 \mathrm{~cm}^{-1}$ for CO ; mass spectrum; m/e (relative intensity), $239\left(\mathrm{M}^{+}, 24\right)$. $238\left(\mathrm{M}^{+}-1,23\right), 211\left(\mathrm{M}^{+}-\mathrm{CO}, 11\right), 198\left(\mathrm{M}^{+}-\mathrm{C}_{3} \mathrm{H}_{5}, 100\right), 185$ (53). 156 (quinolinylCO ${ }^{\prime}$, 95), 128 (quinolinyl' ${ }^{\prime}$ (100).

# Carbon-13 Two Dimensional INADEQUATE Experiment of Cholestane 

Sueg-Geun Lee

Korea Research Institute of Chemical Technology. P.O. Box 9, Daedeogdanji, Taejon 305.606

Received September 21, 1992

Cholestane (i) is one of the most important parent compound in the family of steroids which are of great biological interests, and still new steroids are continuously being isolated from plants. Because many of their proton resonances fall in a fairly narrow shift range, the carbon chemical shifts are in general far more informative than proton resonances for structural analysis of steroids. Therefore, the early study of steroids was concentrated on the carbon-13 NMR and also was greatly iacilitated by using many substitution products which permitted a reasonable assignment of the carbon resonances in terms of the known substitution effects on conformationally fixed cyclohexane rings. ${ }^{1-4}$ The analysis of the carbon- 13 spectra of a series of steroids by Roberts and his co-workers is a particularly elegant example of this application and many of their data provide a good basis for the carbon-13 spectra of related materials. ${ }^{1.2}$ However, the contradictory assignments in the parent hydrocarbon, cholestane (1), exist in the literature; such as carbons 12 and $166^{1.3 .4}$ In addition, the chemical shifts of carbons 4 and 6 , of carbons 18 and 19 , and of carbons 10 and 22 are reported to be overlapped in the 100 MHz NMR ( 25 MHz at carbon). ${ }^{3.4}$ Although unambiguous assignment of the parent compound, 1 , is absolutely prerequisite before attempting the exact evaluation of substitution effects, no high field NMR of cholestane (1) has ever been studied.

In order to elucidate the carbon skeleton of organic molecules, there are numerous indirect ways nowadays. ${ }^{5}$ For example, in the case of protonated carbons the combination of COSY and HETCOR or long range HETCOR experiment provides the necessary information required to establish the carbon connectivity. ${ }^{5}$ Although the application of long range HETCOR for the assignment of quaternary carbons is very useful, the result may be ambiguous because of the uncertainties regarding the bond length of the polarization pathway. In addition, this indirect approach fails and some ambiguities remain further in the assignment of carbon resonances when the proton spectra do not exhibit well resolved

Cholestane (1)
