Received July 16, 1994

Reactions of *mer, trans*- $\text{Re}(\equiv\text{NC}_6\text{H}_5)(\text{PPh}_3)_2\text{Cl}_3$ , **I**, with  $\text{PMe}_3$  and  $\text{P}(\text{OMe})_3$  at room temperature, led to *mer, trans*- $\text{Re}(\equiv\text{NC}_6\text{H}_5)(\text{PPh}_3)(\text{PMe}_3)\text{Cl}_3$ , **II**, and *fac*- $\text{Re}(\equiv\text{NC}_6\text{H}_5)(\text{PPh}_3)(\text{P}(\text{OMe})_3)\text{Cl}_3$ , **III**, respectively. The crystal structures of **II** and **III** were determined through X-ray diffraction. **II** crystallizes in the orthorhombic system, space group  $Pna2_1$  with cell parameters  $a = 19.379(4) \text{ \AA}$ ,  $b = 11.867(2) \text{ \AA}$ ,  $c = 12.676(3) \text{ \AA}$ , and  $Z = 4$ . Least-squares refinement of the structure led to a  $R(wR_2)$  factor of 0.0251 (0.0621) for 2203 unique reflections of  $I > 2\sigma(I)$  and for 306 variables. **III** crystallizes in the monoclinic system, space group  $P2_1/n$  with cell parameters  $a = 11.399(3) \text{ \AA}$ ,  $b = 14.718(4) \text{ \AA}$ ,  $c = 17.558(5) \text{ \AA}$ ,  $\beta = 97.79(2)^\circ$ , and  $Z = 4$ . Least-squares refinement of the structure led to a  $R(wR_2)$  factor of 0.0571 (0.1384) for 3739 unique reflections of  $I > 2\sigma(I)$  and for 344 variables. Structural studies showed that the relative orientations of the two phosphines in both complexes are different, probably due to the differences in the coordinating abilities between  $\text{PMe}_3$  and  $\text{P}(\text{OMe})_3$  to the 5-coordinate fluxional intermediate.

### Introduction

Since 1959 transition-metal imido (or nitrene) complexes have been reported, including derivatives of Group 4-8 metals, and have attracted continuous interest.<sup>1</sup> They have been postulated to be important intermediates in a several industrial catalytic processes.<sup>2-4</sup> Bergman and his workers recently reported an insertion of CO into an  $\text{Ir} \equiv \text{N}$  bond in  $\text{Cp}^*\text{Ir}(\equiv\text{N}^t\text{Bu})(\text{Cp}^* = \text{C}_5(\text{CH}_3)_5)$ , which is the first carbonylation of a terminal imido ligand to give an isocyanate complex.<sup>5</sup> Very recently, our group reported the preparation and structure of *fac*- $\text{Re}(\equiv\text{NPh})(\text{CO})(\text{PPh}_3)\text{Cl}_3$ , by treating *mer, trans*- $\text{Re}(\equiv\text{NPh})(\text{PPh}_3)_2\text{Cl}_3$ , **I**, with CO Eq. (1).<sup>6</sup> Our initial purpose in that experiment is to induce an insertion of CO into a  $\text{Re} \equiv \text{N}$  bond to transform a terminal nitrene into an isocyanate group. The results of studies, however, revealed that the product results from substitution instead of insertion. We decided to modify the ligand environments of **I** by replacing  $\text{PPh}_3$  with the smaller ligands,  $\text{PMe}_3$  and  $\text{P}(\text{OMe})_3$ , possessing the better coordinating ability. We report here the preparations and structures of *mer, trans*- $\text{Re}(\equiv\text{NC}_6\text{H}_5)(\text{PPh}_3)(\text{PMe}_3)\text{Cl}_3$ , **II**, and *fac*- $\text{Re}(\equiv\text{NC}_6\text{H}_5)(\text{PPh}_3)(\text{PMe}_3)\text{Cl}_3$ , **II**, and *fac*- $\text{Re}(\equiv\text{NC}_6\text{H}_5)(\text{PPh}_3)(\text{P}(\text{OMe})_3)\text{Cl}_3$ , **III**.

### Experimental

Unless otherwise stated, all the reactions have been performed with standard Schlenk line and cannula techniques under an argon atmosphere. Air-sensitive solids were manipulated in a glove box filled with an argon gas. Glassware was either flame-dried or oven-dried. Benzene, diethyl ether,

tetrahydrofuran (THF), and hydrocarbon solvents were stirred over sodium metal and distilled under vacuum. NMR solvents ( $\text{C}_6\text{D}_6$  and  $\text{CDCl}_3$ ) were freeze-pump-thaw degassed before use and stored over molecular sieves under argon. Aniline was distilled from  $\text{CaH}_2$  and stored under argon.  $\text{Re}$ , trimethylphosphine ( $\text{PMe}_3$ ;  $\text{Me} = \text{CH}_3$ , 1 M in toluene), trimethylphosphite ( $\text{P}(\text{OMe})_3$ ), and triphenylphosphine ( $\text{PPh}_3$ ;  $\text{Ph} = \text{C}_6\text{H}_5$ ) were purchased from Aldrich Co. and used as received.  $\text{Re}(\equiv\text{NC}_6\text{H}_5)(\text{PPh}_3)\text{Cl}_3$ , **I**, was prepared by the literature method.<sup>7</sup>

<sup>1</sup>H and <sup>13</sup>C NMR spectra were recorded with a Hitach 1100 60-MHz spectrometer and a Varian 200-MHz spectrometer with reference to tetramethylsilane. IR spectra were recorded with a Nicolet 205 FTIR spectrophotometer. Melting points were measured with a Thomas Hoover capillary melting point apparatus without calibration. Elemental analyses have been performed by Korea Basic Science Center.

**Preparation of  $\text{Re}(\equiv\text{NC}_6\text{H}_5)(\text{PPh}_3)(\text{PMe}_3)\text{Cl}_3$ , **II**.** 0.30 g (0.33 mmol) of **I** and 0.66 ml (0.66 mmol) of  $\text{PMe}_3$  (1.0 M in toluene) in 60 ml of benzene were stirred for 36h at room temperature, and then the solvent was removed under vacuum. The resulting green oily product had been stirred in diethyl ether (30 ml) for 2h at room temperature to give green solids. The resulting solids were filtered, washed with benzene (30 ml  $\times$  1) and hexanes (30 ml  $\times$  3), and then dried under vacuum to give 0.10 g (0.13 mmol, 39.4%) of **II**. The product recrystallized from acetone/hexanes. <sup>1</sup>H-NMR ( $\text{CDCl}_3$ )  $\delta$  1.650 (9H, dd,  $J_{\text{P-H}} = 10.87 \text{ Hz}$ ,  $J_{\text{P-H}} = 1.22 \text{ Hz}$ ,  $\text{PMe}_3$ ), 7.007-7.858 (20H, m), <sup>13</sup>C{<sup>1</sup>H} NMR ( $\text{CDCl}_3$ )  $\delta$  12.96 (d,  $J_{\text{P-C}} = 138 \text{ Hz}$ ,  $\text{PMe}_3$ ), 121.20, 127.79, 127.99, 128.52, 129.59, 130.13, 134.63, 134.81. Anal. Calcd for  $\text{C}_{27}\text{H}_{29}\text{NP}_2\text{Cl}_3\text{Re}$ : C, 44.91; H, 4.06; N, 1.94. Found: C, 44.62; H, 4.16; N, 1.97. mp. = 178-180  $^\circ\text{C}$ . **X-ray Structure Determination.** All X-ray data were collected with use of an Enraf-Nonius CAD4 automated diffractometer equipped with a Mo X-ray tube and a graphite crystal monochromator. Details on crystal and intensity data are given in Table 1. The orientation matrix and unit cell parameters were determined from 25 machine-centered reflections with 20<2θ<30°. Axial photographs were used to verify the unit cell choice. Intensities of three check reflections were monitored after every 1h during data collection. Data were corrected for Lorentz and polarization effects. Decay corrections were made. The intensity data were empirically corrected with Ψ-scan data. All calculations were carried out on the personal computer with use of the SHELXS-86<sup>8</sup> and SHELXL-93<sup>9</sup> programs.

A green crystal of **II**, shaped as a block, of approximate dimensions 0.3×0.3×0.4 mm, was used for crystal and intensity data collection. The unit cell parameters and systematic

**I**, reacted with  $\text{PMe}_3$  at room temperature to give *mer, trans*- $\text{Re}(\text{NPh})(\text{PPh}_3)(\text{PMe}_3)\text{Cl}_3$ , **II**, which recrystallized from acetone/hexanes Eq. (2). **II** is air-stable in a solid form but unstable in solutions. For instance, **II** changed its color from green to brown after 48h in such solvents as dichloromethane and benzene. This situation was also observed for the complex *fac*- $\text{Re}(\text{NPh})(\text{PPh}_3)(\text{CO})\text{Cl}_3$  which was previously prepared by our group.<sup>6</sup> *Fac*- $\text{Re}(\text{NPh})(\text{PPh}_3)(\text{P}(\text{OMe})_3)\text{Cl}_3$ , **III**,

was obtained by a similar reaction, and recrystallized from  $\text{CH}_2\text{Cl}_2$ /hexanes Eq. (3). **III** was originally prepared by reacting  $\text{Re}(\text{O})(\text{PPh}_3)(\text{P}(\text{OMe})_3)\text{Cl}_3$  with aniline.<sup>10</sup> **III** also appeared to be unstable in such solvents as  $\text{CH}_2\text{Cl}_2$  and THF.

In  $^{13}\text{C}$  NMR spectra, both **II** and **III** show a doublet for  $\text{PMe}_3$  ( $\delta$  12.96, d,  $J_{\text{P-C}}=138$  Hz) and  $\text{P}(\text{OMe})_3$  ( $\delta$  55.67, d,  $J_{\text{P-C}}=34$  Hz), due to carbon-phosphorus couplings. In  $^1\text{H}$  NMR spectra, methyl protons of  $\text{PMe}_3$  in **II** give rise to a sharp doublet of doublets at  $\delta$  1.65, indicating that, first, the protons of  $\text{PMe}_3$  are strongly coupled to the phosphorus of  $\text{PMe}_3$  ( $J_{\text{P-H}}=10.87$  Hz), and second, weakly coupled to the phosphorus of  $\text{PPh}_3$  *trans* to  $\text{PMe}_3$  ( $J_{\text{P-H}}=1.22$  Hz). In  $^1\text{H}$  NMR spectra, the splitting patterns of phosphine protons of metal bisphosphine complexes in which phosphines are particularly identical alkyl phosphines, are known to be sensitive to the relative orientations of the two phosphines.<sup>11</sup> For example, if two phosphine ligands are *cis*, a doublet for the alkyl protons is observed. On the other hand, if they are *trans*, a distorted triplet with a broad central peak is observed, due to the virtual coupling by which alkyl protons appear to be coupled both to its own and to the *trans*-phosphorus nucleus about equally. Although the two phosphines in **II** are *trans*,  $^1\text{H}$  NMR spectra of **II** exhibits a doublet of doublets for methyl protons instead of a triplet, probably because of the inequivalent phosphines.  $^1\text{H}$  NMR spectra **III** show a sharp doublet at  $\delta$  3.69, which indicates a *cis*-orientation of  $\text{PPh}_3$  and  $\text{P}(\text{OMe})_3$  ligands. The relative orientations of two phosphines in **II** and **III** were concretely confirmed by X-ray diffraction studies, as described later.

The relative orientations of the phosphine ligands in **II** and **III** invoke a fundamental question as to how they were formed. Since the starting material **I** is an 18-electron saturated complex, complex **II** and **III** might be produced from the same 5-coordinate intermediate, which was formed by dissociation of  $\text{PPh}_3$  (Scheme 1). In addition, the intermediate appeared to be fluxional, considering the relative orientations of two phosphine ligands in **II** and **III**. In other words, **II** was formed by addition of  $\text{PMe}_3$  before the intermediate rearranged and **III** was formed after the intermediate rearranged. These results might be explained in terms of the differences in coordinating abilities between  $\text{PMe}_3$  and  $\text{P}(\text{OMe})_3$ . Trialkylphosphines are known to have more powerful coordinating ability than the corresponding trialkylphosphites.<sup>12</sup>  $\text{PMe}_3$ , with the better coordinating ability, appeared to bind to the intermediate to give **II** before the ligand rearrangement, with the retention of configuration around the rhenium metal. On the other hand,  $\text{P}(\text{OMe})_3$ , with the less coordinating ability compared to  $\text{PMe}_3$ , seemed to react somewhat slowly with the fluxional intermediate which has enough time to rearrange. This type of rearrangement of the intermediate **A** (Scheme 1) was also observed in the preparation of *fac*- $\text{Re}(\text{NPh})(\text{PPh}_3)(\text{CO})\text{Cl}_3$  from the reaction of **I** with  $\text{CO}$ .<sup>6</sup> At this point we cannot clearly explain how

**Figure 1.** ORTEP drawing of **II** showing the atom-labeling scheme and 50% probability thermal ellipsoids.

the *fac*-orientation of the three Cl ligands in **III** was preferentially formed. However, since the other three ligands in **III**,  $\text{P}(\text{OMe})_3$ ,  $\text{PPh}_3$ , and  $\text{NPh}$ , are relatively strong *trans*-influence ligands, they are expected to prefer *cis*-orientations to each other. These *cis*-orientations maybe play an important role in determining the direction of the ligand rearrangement of the intermediate to produce the *fac*-orientation of the three Cl ligands.

**Structure of **II** and **III**.** As shown in Figure 1, 2, compound **II** has a  $\text{NPh}$  group, three *mer*-Cl atoms and *trans*-phosphine ligands, and compound **III** has a  $\text{NPh}$  group, three *facial*-Cl atoms, and *cis*-phosphine ligands. **II** shows a more distorted octahedral geometry than the starting material **I**<sup>13</sup> (Table 3). For example, five atoms (Re, N, C11, C12, C13) on the basal plane in **I** and **II** are coplanar within  $\pm 0.01$  Å,  $\pm 0.05$  Å, respectively, and the bond angles of P-Re-P are  $174.1(1)^\circ$  in **I** and  $172.5(1)^\circ$  in **II**. The distortion may result from replacing one  $\text{PPh}_3$  in **I** by a smaller  $\text{PMe}_3$  group.<sup>12</sup> The fact that the dihedral angles between the basal plane (Re, N, C11, C12, C13) and a phenyl ring of phenylimido are  $5.2(3)^\circ$  in compound **I** and  $12.5(5)^\circ$  in compound **II** also supports the steric repulsion among the phenylimido phenyl ring and two phosphine ligands. In comparison to the

**Figure 2.** ORTEP drawing of **III** showing the atom-labeling scheme and 50% probability thermal ellipsoids.

starting material **I**, the bond distance of Re-N became shorter from 1.726(6) Å to 1.711(6) Å and the bond angle of Re-N-C(Ph) became essentially linear from 172.6(6)° to 176.0(6)°, indicating that the Re-N bond in **II** is strengthened and has a more triple bond character, and therefore the nitrogen atom has more *s*-character.<sup>1a</sup>

On the other hand, five atoms (Re, N, C11, C12, P2) on the basal plane in **III** are coplanar within  $\pm 0.02$  Å, and the dihedral angle between the basal plane and the phenylimido phenyl ring is 44.8(4)°, which suggests that the steric repulsion among the phenylimido phenyl ring, PPh<sub>3</sub> and P(OMe)<sub>3</sub> is very high. The bond distance (1.710(8) Å) of Re-N in **III** is similar to that (1.711(6) Å) in **II**, but the bond angle of Re-N-C(Ph) (167.9(7)°) in **III** is more distorted from linearity than that (176.0(6)°) in **II**. Structural studies of both **II** and **III** show that the nitrogen atom in both complexes has more *s*-character than that in **I**, and that the *cis*-configuration of PPh<sub>3</sub> and P(OMe)<sub>3</sub> in **III** results in the high steric congestion around the central metal to break more severely the coplanarity between the basal plane and NPh.

The bond distances of Re-Cl (2.419(2) Å in **II**, 2.419(3) Å in **III**), *trans* to N, are longer than that in **I** (2.402(2) Å), suggesting that the imido group has an enhanced *trans*-influence effect in **II** and **III**. The average bond distance of Re-Cl (2.421(6) Å for **II**, 2.423(3) Å for **III**), *trans* to phosphine, in **II** and **III** became longer than that in **I** (2.409(4) Å), in spite of substitution of a smaller PMe<sub>3</sub> (cone angle,  $\theta = 118^\circ$ ), P(OMe)<sub>3</sub> ( $\theta = 107^\circ$ ) for a larger PPh<sub>3</sub> ( $\theta = 145^\circ$ ).<sup>12</sup> These results suggest that an electronic effect of PMe<sub>3</sub> and P(OMe)<sub>3</sub>, in addition to their steric effect, on the geometry of **II** and **III** may also be important. The metal-halide bond in a high-valent metal complex frequently has a multiple bond character due to  $\pi$ -bonding from a lone pair of electrons to a vacant *d*-orbital of the metal in the high oxidation state.<sup>14</sup> The elongated bond distances of Re-Cl in **II** and **III** might be explained by the presence of both PR<sub>3</sub> (R = Me in **II**, OMe in **III**) and a more *sp*-hybridized imido group, which

can donate the electron density to the electron-deficient Re metal in the high oxidation state of +5. The Re-P bond distances (2.421(2) Å for Re-PMe<sub>3</sub>, 2.465(3)-2.503(2) Å for Re-PPh<sub>3</sub>) agree with known values (2.324-2.470 Å, 2.472-2.505 Å, respectively).<sup>15</sup> The Re-P(PPh<sub>3</sub>) bond distance of 2.503(2) Å in **II**, *trans* to PMe<sub>3</sub>, is longer than that (2.465(3) Å) in **III**, *trans* to Cl, which can be explained on the basis of the known fact that PMe<sub>3</sub> is a stronger *trans*-influence ligand than Cl.<sup>16</sup>

In summary, we prepared Re(NPh)(PPh<sub>3</sub>)(PR<sub>3</sub>)Cl<sub>3</sub> (PR<sub>3</sub> = PMe<sub>3</sub> for **II**, P(OMe)<sub>3</sub> for **III**) from Re(NPh)(PPh<sub>3</sub>)<sub>2</sub>Cl<sub>3</sub> by replacing one PPh<sub>3</sub> with the corresponding ligands. Structures of these mixed-phosphine complexes have been determined through X-ray diffraction. Structural studies showed that the relative orientations of the two phosphines in both complexes are different, probably due to the differences in the coordinating abilities between PMe<sub>3</sub> and P(OMe)<sub>3</sub> to the 5-coordinate fluxional intermediate.

## pH-Dependent Electrochemical Behavior of N-Monosubstituted-4,4'-Bipyridinium Ions

Joon Woo Park\*, Yuna Kim, and Chongmok Lee

Department of Chemistry, Ewha Womans University, Seoul 120-750, Korea

Received July 19, 1994

The pH-dependent reduction behavior of N-monosubstituted-4,4'-bipyridinium ions (RBPY<sup>+</sup>; R=methyl(C<sub>1</sub>); benzyl; n-octyl; n-dodecyl) has been investigated by electrochemical and spectroelectrochemical techniques. At acidic condition, RBPY<sup>+</sup> is protonated and the protonated species are reduced by two consecutive one-electron processes. The 2e<sup>-</sup> reduced species undergoes a chemical reaction with H<sup>+</sup>. The second-order rate constant (*k<sub>H</sub>*) of the homogeneous chemical process is  $(3.7 \pm 0.3) \times 10^3 \text{ M}^{-1} \text{ s}^{-1}$  for the two electron reduction product of C<sub>1</sub>BPY<sup>+</sup>. At high pH, the electrode reduction of RBPY<sup>+</sup> is one-step 2e<sup>-</sup> transfer process with concomitant addition of H<sup>+</sup>, which is confirmed by cyclic voltammetric study using a microdisk electrode.

### Introduction

N-monosubstituted-4,4'-bipyridinium ions (RBPY<sup>+</sup>) are closely related with N,N'-disubstituted-4,4'-bipyridinium ions (viologens) via the following acid-base equilibrium.

The acidic form has structural similarity to viologens which are very attractive materials as electron-transfer reagent in chemical<sup>1</sup> and photochemical<sup>2</sup> reductions of substrates, solar energy conversion,<sup>3</sup> and electrochromic display.<sup>4</sup> The basic form is a substituted pyridinium and can be considered as a coenzyme NAD<sup>+</sup> analogue. Because of these interesting characters, the pH-dependent electrochemical<sup>5,6</sup> and spectroscopic<sup>7,8</sup> behaviors of the RBPY<sup>+</sup> compounds as well as their ability as electron carriers<sup>9-11</sup> in redox reactions have been investigated. Recently, Ishida *et al.*<sup>11</sup> reported that the interaction between CO<sub>2</sub> and electrochemically reduced species of N-propyl-4,4'-bipyridinium cation (C<sub>3</sub>BPY<sup>+</sup>) activates the electron transfer from the bipyridine ring to CO<sub>2</sub>. They also claimed that C<sub>3</sub>BPY<sup>+</sup> is reduced by 1e<sup>-</sup> process at -1.0 V (*vs* SCE) in acetonitrile media. We have been interested in electrochemical behavior of viologens<sup>12,13</sup> and the reactions of the reduced NAD<sup>+</sup>, NADH, and their analogues.<sup>14,15</sup> In this paper, we present the pH-dependent reduction behavior of RBPY utilizing electrochemical and spectroelectrochemical techniques. Cyclic voltammetry (CV) with a microdisk electrode is used to determine the number of elec-

trons transferred in the reduction reactions. Also, the reaction rate of the electrogenerated 2e<sup>-</sup> reduction product of C<sub>1</sub>BPY<sup>+</sup> in acidic medium is determined.

### Experimental

**Materials.** N-monosubstituted-4,4'-bipyridinium (RBPY<sup>+</sup>; R= methyl (C<sub>1</sub>); benzyl (B); n-octyl (C<sub>8</sub>); n-dodecyl (C<sub>12</sub>)) salts were prepared by reacting 4,4'-bipyridine with corresponding alkyl or benzyl halides according to known procedure.<sup>9</sup> Solutions of desired pH were prepared by appropriate mixing of 0.10 M HCl, 0.01 M NaOH+0.09 M NaCl, or 0.01 M Na<sub>2</sub>HPO<sub>4</sub>+0.07 M NaCl solutions. Reverse osmosed water which was further purified by passage through a purification train (Millipore Corp) was used.

**Apparatus and procedures.** Cyclic voltammetry (CV) was carried out with a BAS 100B electrochemical analyzer or a Tacussel PRG 5 potentiostat coupled with a GSTP3 function generator. Glassy carbon electrodes (Metrohm and BAS, area of 0.06-0.07 cm<sup>2</sup>) were polished using 0.1 μm alumina followed by sonication in pure water. A carbon microdisk electrode having a nominal diameter of 11 μm was prepared<sup>16</sup> and used. All potentials are reported against a saturated calomel electrode (SCE) unless otherwise specified. Solutions were purged with nitrogen to remove oxygen. Current was calculated by subtracting the background CV data taken without RBPY<sup>+</sup> from CV data recorded with RBPY<sup>+</sup>. A Hewlett-Packard 8452A diode array spectrophotometer was used to obtain absorption spectra where the potential of the working electrode (ITO coated glass, Delta Technologies) was controlled potentiostatically.
