#### Abstract

New dynemicin A mimics with methyl group $\mathbf{2 a}$ and $\mathbf{2 b}$ were synthesized, and acid-induced hydrolyzed to see an electronic effect of substituent for epoxide opening. The model $\mathbf{2 a}$ with methyl group at C 3 position was more rapidly transformed to diof 16a than 2b with methyl group at C 2 . This result suggests that any substituent at C 3 position plays more important role than any substituent at C 2 position in the dynemicin A mimic activation.

## Introduction

A new type of antibiotics, esperamicin and calicheamicin, was reported by Lederle laboratories ${ }^{1}$ and Bristol-Meyers' researchers, ${ }^{2}$ respectively in 1987. These drugs have been received increasing attention because of their extremely potent antitumor activity and unusual structure containing enediyne system. ${ }^{3}$ The dynemicin A (1) ${ }^{4}$ isolated from micromonospora chersina also showed a potent antitumor activity in vitro and in vivo. Structurally, this drug was characterized as a hybrid molecule of two typical chemotypes of antineoplastic agents, enediyne and anthraquinone. The pronounced cytotoxic activity of these compounds has been attributed to their ability to undergo Bergman cyclization to give a phenylene diradical which initiates DNA cleavage. ${ }^{5}$ Cycloaromatization for 1 is triggered by epoxide opening induced by developing electron density at $\mathrm{C}-9$. This suggestion that epoxide opening is a critical step of the drug activation has been supported by the results of molecular modeling and mechanistic studies. ${ }^{67}$ Accordingly, for the model compound (i.e., 2a) the use of proper substituent on benzene ring will give an effect on electron density of $\mathrm{C10a}$ and then, epoxide opening and cycloaromatization will be able to be controlled. In this paper, we describe the syntheses and acid-induced Bergman cyclization of tricyclic dynemicin A models $2 a$ and 2b.

## Results and Discussion

Synthesis of Dynemicin A Models. Scheme 1 and 2 summarize the construction of new dynemicin A model 2a starting 3 -methyl-7,8,9,10-tetrahydrophenanthridine (3) ${ }^{8}$ using a typical preparation method ${ }^{9,10}$ for the dynemicin A
model compounds.
The first strategy to make $\mathbf{2 a}$ is the $\mathbf{C} 6$ and C 10 functionalization of compound 3 . The treatment of $\mathbf{3}$ with $m$-chloroperoxybenzoic acid ( $m \mathrm{CPBA}$ ) in dichloromethane gave the $N$. oxide, which was vigorously stirred to give the acetate 4. This acetate was converted to the silyl ether 6 in overall high yield by conventional method via base hydrolysis of product 5. Introduction of acetylene at C6 with ethynylmagnesium bromide and protection of N5 with phenyl chloroformate transformed compound 6 to diastereomeric mixture 7. Continuously, treatment of 7 with mCPBA yielded the epoxide 8, which was converted to the ketone 10 via alcohol 9 by desilylation, followed by oxidation with pyridinium dichlorochromate (PCC) (Scheme 2). Coupling of compound 10 and vinyl chloride 11 using $\mathrm{Pd}(0)-\mathrm{Cu}(\mathrm{I})$ catalysis afforded an enediyne product 12. On the other hand, even though direct cyclization of 12 with CsF to give alcohol 14 via 13 was tried, only desilylated product $\mathbf{1 3}$ was isolated in relatively good yield. ${ }^{11}$ Treatment of 13 with lithium diisopropylamide (LDA) resulted in the formation of 10 -membered enediyne cyclic adduct 14. Finally, the tertiary hydroxy group in 14 was removed to obtain a closer model of dynemicin A. The treatment of alcohol 14 with thiocarbonyldiimidazole

in the presence of 4 -(dimethylamino)pyridine (DMAP) gave the compound 15, which was reduced to the desired compound 2 a by $n-\mathrm{Bu}_{3} \mathrm{SnH}$ and $2,2^{\prime}$-azobis(isobutyronitrile) (AIBN).

Activation of Dynemicin $\mathbf{A}$ models. The tandem acid-induced epoxide opening and Bergman cyclization of new models was performed to examine an electronic effect by methyl group (Scheme 3). Compounds 2a and $\mathbf{2 b}$ with methyl group at C 3 and C 2 positions were treated with $p$ toluenesulfonic acid in benzene/1,4-cyclohexadiene (3/1) at $40^{\circ}$ C. Expectedly, 2 a and $\mathbf{2 b}$ gave the aromatized products $16 a$ and 16b, respectively via tandem epoxide opening and Bergman cyclization. Table 1 shows the reaction time and yields for the enediyne models. The unsubstituted compound 2c was also activated to compare the reaction profile with two methyl substituted models under the same condition. ${ }^{10}$ Interestingly, epoxide opening for the three compounds showed a significant rate difference. The order of reactivity was $\mathbf{2 a}, \mathbf{2 b}$ and 2c. Moreover, compound 2a with methyl group at para position to the internal epoxide underwent epoxide opening more rapidly than $\mathbf{2 b}$ with methyl group at meta position. These results suggest that the methyl group partici-

pates in the epoxide opening as an activator, and confirm a known mechanism that epoxide opening triggers Bergman cyclization in dynemicin A chemistry.
In summary, two tricyclic dynemicin A model compounds were easily synthesized from methyl substituted $7,8,9,10$-tetrahydrophenanthridine. In acidic condition, the epoxide of these methyl derivatives was opened with different rate and then, Bergman cyclized to give the aromatized compounds. The fact that 2a is more rapidly hydrolyzed to diol than 2b suggests that C 3 position could have priority to C 2 in the choice of any substituent for new dynemicin mimic development.

Genenral Techiques. Melting points were recorded on a Büchi 512 capillary melting point appratus and were not corrected. NMR spectra were recorded on a Varian Unity Plus FT-300 instrument. IR spectra were recorded on a Perkin Elmer 1430 IR spectrophotometer.

All reactions were monitored by thin-layer chromatography carried out on 0.25 mm E. Merck silica gel plates ( $60 \mathrm{~F}-254$ ) under UV light. Preparative thin layer chromatography was performed on $0.5 \mathrm{~mm} \times 20 \mathrm{~cm} \times 20 \mathrm{~cm}$ E. Merck silica gel plates ( $60 \mathrm{~F}-254$ ). E. Merck silica gel (60, particle size $0.040-$ 0.063 mm ) was used for flash chromatography.
