Received April 8, 2004

Kinetic studies of the pyridinolysis ($\text{XC}_5\text{H}_4\text{N}$) of aryl dithiomethylacetates ($\text{CH}_3\text{CH}_2\text{C}(=\text{S})\text{SC}_6\text{H}_4\text{Z}$, **1**) are carried out in acetonitrile at 60.0 °C. A biphasic Brønsted plot is obtained with a change in slope from a large ($\beta_X \cong 0.8$) to a small ($\beta_X \cong 0.2$) value at $\text{p}K_a^\circ = 5.2$, which is attributed to a change in the rate limiting step from breakdown to formation of a zwitterionic tetrahedral intermediate, T^\ddagger , in reaction path as the basicity of the pyridine nucleophile increases. This mechanism is supported by the change of the cross-interaction constant ρ_{XZ} from a large positive ($\rho_{XZ} = +1.36$) for the weakly basic pyridines to a small negative ($\rho_{XZ} = -0.22$) value for the strongly basic pyridines. The magnitudes of ρ_Z and activation parameters are also consistent with the proposed mechanism.

Key Words : Nucleophilic substitution reaction, Pyridinolysis, Cross-interaction constant, Zwitterionic tetrahedral intermediate, Stepwise mechanism

Introduction

The mechanisms of the aminolysis of aryl esters and carbonates have been well established.¹ These reactions are known to proceed stepwise through a zwitterionic tetrahedral intermediate, T^\ddagger . The existence of the intermediate has been deduced from curved Brønsted-type plots. A biphasic dependence of the rate on the amine basicity showing a change of slope from a large ($\beta_{\text{nuc}} \geq 0.8$) to a small ($\beta_{\text{nuc}} \approx 0.1-0.3$) value at $\text{p}K_a^\circ$, where the amine and leaving group have the same expulsion rates from T^\ddagger , has been attributed to a change in the rate-limiting step from breakdown to formation of a tetrahedral intermediate as the basicity of the amine increases.²⁻⁵

The aminolysis of dithio esters and carbonates has been studied in aqueous and acetonitrile solutions.⁶ An important advantage of using an acetonitrile medium is that there are no complications arising from a kinetically important proton transfer from T^\ddagger to the amine.⁷ In water, the rate of proton transfer, k_{H} , may be faster than that of expulsion of arenethiolate from T^\ddagger so that the rate law becomes complex.⁷ This kinetic complexity encountered in the aminolysis of dithiocarboxylates (and also thiono) compounds in water is known to originate from the weak π bond energy of CS (compared to CO) which causes the difficulty in reforming the CS double bond when T^\ddagger break down expelling either the amine or ArS^- .⁷

The breakpoint, $\text{p}K_a^\circ$, has been shown to depend on various factors which influence the relative rates of expulsion of the nucleophile, amine, (k_a) and leaving group (k_b) from a tetrahedral intermediate,^{8,9} k_{-a}/k_b in eq. (1). Keeping other conditions constants the breakpoint, $\text{p}K_a^\circ$, occurs at a lower $\text{p}K_a$ value due to a decrease in k_{-a}/k_b : (i) as the leaving ability of SLZ increases,¹⁰ (ii) as the nonleaving R becomes stronger electron donating group,¹¹ (large k_b), (iii) as the amine nature changes successively from a primary (e.g. benzylamine) \rightarrow secondary (alicyclic) \rightarrow aniline \rightarrow pyridine¹² (successive decreases in k_{-a}/k_b), (iv) by substituents of S for O in T^\ddagger , i.e., for thiono than carbonyl esters,¹³ (decrease in k_{-a} more than k_b), (v) in aqueous than aprotic solvent¹⁴ (decrease in k_{-a}).

X = 4-CH₃O, 4-CH₃, 3-CH₃, 4-C₆H₅CH₂, H, 3-C₆H₅, 3-CH₃CO, 3-Cl, 4-CH₃CO, 4-CN, and 3-CN
Z = 4-CH₃, H, 4-Cl, and 4-Br

In this work, we report the result of kinetic studies on the pyridinolysis of aryl dithiomethylacetates in acetonitrile at 60.0 °C, eq. (2). The aim is to complete the previous studies¹⁵ on the aminolysis mechanism of aryl dithiomethylacetates and to further clarify the influence of the amine nature on the $\text{p}K_a^\circ$ value. As an additional criterion for the elucidation of the mechanism, we determined the cross-interaction constant,¹⁶ ρ_{XZ} in eqs. (3a) and (3b), where X and Z represent substituents in the nucleophile and leaving group, respectively.

$$\log(k_{XZ}/k_{\text{H}}) = \rho_X\sigma_X + \rho_Z\sigma_Z + \rho_{XZ}\sigma_X\sigma_Z \quad (3a)$$

^aThe s values were taken from C. Hansch, A. Leo, and R. W. Taft, *Chem. Rev.* **1991**, *91*, 165. The pK_a values of pyridine in water at 25 °C were taken from: (a) Albert, A.; Serjeant, F. P. *The determination of Ionization Constants*; 3rd ed.; Chapman and Hall: New York, 1984; pp 154-155. (b) Dean, J. A. *Handbook of Organic Chemistry*; McGraw-Hill: New York, 1987; Chapter 8. (c) Fischer, A.; Galloway, J. A.; Vaughan, J. *J. Chem. Soc.* **1964**, 3591. (d) The pK_a values of X-3-C₆H₅ and X-4-CH₃CO were taken from ref 25. ^bFor X=4-CH₃O, 4-CH₃, 3-CH₃, 4-C₆H₅CH₂, and H ^cCorrelation coefficients are better than 0.996 in all cases. ^dCorrelation coefficients are better than 0.995 in all cases. ^eFor X=H, 3-C₆H₅, 3-CH₃CO, 3-Cl, 4-CH₃CO, 4-CN, 3-CN. ^fCorrelation coefficients are better than 0.998 in all cases. ^gCorrelation coefficients are better than 0.996 in all cases. ^hCorrelation coefficients are better than 0.973 in all cases. ⁱCorrelation coefficient is 0.975. ^lCorrelation coefficient is 0.995.

$$\rho_{XZ} = \partial \rho_X / \partial \sigma_Z = \partial \rho_Z / \partial \sigma_X \quad (3b)$$

Results and Discussion

The rate law obtained in the present reactions is given by eqs. (4) and (5), where ArS⁻ is the leaving group, k_{obs} is the pseudo-first-order rate constant, k_0 and k_N are the rate constants for solvolysis and pyridinolysis of the substrate, respectively, and [Py] and [S] represent the pyridine and substrate concentrations, respectively. The value of k_0 was negligible in acetonitrile, $k_0 \cong 0$.

$$d[\text{ArS}^-]/dt = k_{\text{obs}}[\text{S}] \quad (4)$$

$$k_{\text{obs}} = k_0 + k_N[\text{Py}] \quad (5)$$

The second-order rate constants for pyridinolysis (k_N) were obtained as the slopes of plots of eq. (5). These values, together with those of the pK_a of the conjugate acids of the pyridines, are summarized in the Table 1. The rate of aryl dithiomethylacetate with pyridine nucleophiles (e.g. $k_N = 3.79 \times 10^{-3} \text{ M}^{-1} \text{ s}^{-1}$ at 60.0 °C with Z = H) are slower than aryl dithioacetate with pyridine ($k_N = 5.08 \times 10^{-3} \text{ M}^{-1} \text{ s}^{-1}$ at 60.0 °C with Z = H).¹⁵ The higher rates observed with CH₃ than C₂H₅ can be explained by the steric effect of the ethyl group. The Brønsted plots using the k_N and pK_a values in Table 1 were obtained as presented in Figure 1. The slopes are collected in Table 1, where the Hammett coefficients, $\rho_X (= \rho_{\text{nuc}})$ and $\rho_Z (= \rho_{\text{le}})$, and the cross-interaction constant, ρ_{XZ} , are also presented. Close examination of ρ and β values, shows that the magnitude of ρ_X and β_X are somewhat larger

**Figure 1.** Brønsted plots for the reactions of Z-aryl dithiomethylacetates with X-Pyridines in acetonitrile at 60.0 °C.

with CH₃ than that with C₂H₅. These differences reflect that the TS with CH₃ is somewhat tighter than that with C₂H₅. Although the β_X values are based on the plots of $\log k_N(\text{MeCN})$ vs $pK_a(\text{H}_2\text{O})$, they can provide reasonable guides since a near constant $\Delta pK_a (= pK_a(\text{MeCN}) - pK_a(\text{H}_2\text{O}) \cong 7.5)$ was experimentally¹⁷ as well as theoretically¹⁸ found and the slopes will remain practically the same irrespective of whether $pK_a(\text{H}_2\text{O})$ or $pK_a(\text{MeCN})$ is used in the Brønsted correlation. We note that the Brønsted plots in Figure 1 are biphasic with a change in the slope. For Z = H the slope

changes from $\beta_X = 0.78$ to 0.25 at the breakpoints $pK_a^0 = 5.2$ as the basicity of pyridine increases. The magnitude of β_X is somewhat smaller than those ($\beta_X \geq 0.8$)¹⁹ normally obtained but is well within the range ($\beta_X \geq 0.7$ - 0.8 in water²⁰ and 0.6 - 0.7 in acetonitrile²¹) of the corresponding values for the stepwise reactions with rate-limiting expulsion of leaving group. For example, in the aminolysis of ethyl S-aryl thiolcarbonates with secondary alicyclic amines in water the slopes were $\beta_X = 0.7$ - 0.8 ,²⁰ and in the pyridinolysis of S-phenyl 4-nitrobenzoates in acetonitrile the slopes were $\beta_X = 0.6$ - 0.7 ,²¹ both which were consistent with a stepwise mechanism where the breakdown of a zwitterionic tetrahedral intermediate, T^\pm , is rate-determining. The $\beta_X = 0.25$ obtained for more basic pyridines in Table 1 is also consistent with a stepwise mechanism in which the formation of T^\mp is rate-limiting.^{19a} In the pyridinolysis of aryl dithioacetates, $CH_3C(=S)SC_6H_4Z$, a biphasic plot with a change of slope from $\beta_X \cong 0.9$ to a small value of $\beta_X \cong 0.4$ was observed with a breakpoint at $pK_a^0 = 5.2$.²²

On the other hand, in the reactions of **1** the β_X values were 1.5 - 2.8 and 0.9 - 1.2 with benzylamines (at -35.0 °C) and anilines (at 45.0 °C), respectively¹⁵ and no breakpoints were observed. This means that the breakpoints are at $pK_a^0 \geq 9.7$ (the highest pK_a used: 4-methoxybenzylamine) and $pK_a^0 \geq 5.4$ (the highest pK_a used: 4-methoxyaniline) for the reactions with benzylamines and anilines, respectively. The decreasing pK_a^0 value which is related to the decrease in the k_{-a}/k_b ratio in the order benzylamine (≥ 9.7) > aniline (≥ 5.4) > pyridine ($=5.2$) is consistent with the general sequence of the rate of amine expulsion (k_{-a}) from the tetrahedral intermediate, primary amines > secondary alicyclic amines > anilines > pyridines.²³ For the aminolysis of **1** the breakpoint, $pK_a^0 (=5.2)$, can be experimentally observed only in the reactions with pyridines since the pK_a^0 value is higher than the basicities of amines used in the reactions with benzylamines and anilines. This is why a biphasic plots with a clear-cut breakpoint, pK_a^0 , is often observed in the aminolysis with pyridine nucleophiles, as in the pyridinolysis of aryl dithioacetates²¹ and aryl dithiomethylacetates in this work, both at $pK_a^0 = 5.2$. There are other reasons of the relatively low pK_a^0 value ($=5.2$) for the two pyridinolysis of the dithio series: (i) Thiono (S^-) rather than carbonyl (O^-) series leads to a lower pK_a^0 due to a decrease in the k_{-a}/k_b ratio, since the lower proclivity of S^- than O^- in T^\pm to form a double bond and expel a leaving group leads to a slower amine expulsion from T^\mp (smaller k_{-a}) relative to ArS^- leaving (k_b).¹ For example, the reactions of benzylamines with S-phenyl acetates,²⁴ $CH_3C(=O)SC_6H_4Z$, in acetonitrile proceed by a stepwise mechanism with rate-limiting expulsion of $ZC_6H_4S^-$ leaving group ($pK_a^0 \geq 9.7$) from T^\mp but those with aryl dithioacetates, $CH_3C(=S)SC_6H_4Z$ (**2**), proceed by rate-limiting formation of T^\pm ²⁵ ($pK_a^0 \leq 9.14$; the lowest pK_a used: 4-chlorobenzylamine) (ii) Thiophenoxide leaving groups ($ZC_6H_4S^-$) used have lower basicities than phenoxide leaving groups ($ZC_6H_4O^-$) for the same Z, and hence k_b should be greater (decrease in k_{-a}/k_b) leading to a lower pK_a^0 than the corresponding esters with a phenoxide

leaving group.²⁶

In contrast there are also other factors in favor of a higher pK_a^0 for the present reaction series: (i) Aprotic solvent, MeCN, favors amine expulsion (larger k_{-a}) to form ester compared to aqueous solution by stabilizing the TS for the breakdown of T^\pm to form uncharged products relative to that for the formation of anionic leaving group and cationic amide.¹⁴ This will raise the k_{-a}/k_b ratio and hence leads to a higher pK_a^0 value, (ii) An electron donating acyl group, R, results in a rate increase²⁷ in the stepwise reactions where leaving group expulsion is rate-determining, but favors the expulsion of amine relative to thiophenoxide anion, *i.e.*, k_{-a}/k_b increase.¹¹ In the reactions of aryl dithio series, $RC(=S)SC_6H_4Z$, with anilines, R = C_2H_5 renders a greater rate, $k_N = 3.19 \times 10^{-3} M^{-1}s^{-1}$ (Z = H), at 45.0 °C relative to R = CH_3 ($k_N = 9.46 \times 10^{-4} M^{-1}s^{-1}$ at 50.0 °C, Z = H) and R = C_6H_5 ($k_N = 2.85 \times 10^{-3} M^{-1}s^{-1}$ at 55.0 °C, Z = H).¹⁵ This means that the ethyl group is a stronger electron acceptor than either R = CH_3 or C_6H_5 group and hence the k_{-a}/k_b ratio should be greater with a higher pK_a^0 value than that for the aryl dithio series with R = CH_3 and C_6H_5 . This is indeed evidenced by the mechanistic change over from rate-limiting breakdown of T^\mp with anilines to a stepwise mechanism with rate-limiting formation of T^\pm (*i.e.*, pK_a^0 is at lower values) in the aminolysis of the two dithio compounds (R = CH_3 ²⁵ and C_6H_5 ⁶) with benzylamines in contrast to no mechanistic change, *i.e.*, the stepwise with rate-limiting breakdown of T^\mp , for the aminolysis of ethyl¹⁵ series, with anilines and benzylamines. The pK_a^0 observed ($=5.2$) is then the consequence of balance between these two opposing effects on the k_{-a}/k_b ratio.

The size of ρ_Z in Table 1 also reflects the mechanistic change. The magnitudes of ρ_Z change from larger values, $\rho_Z = 1.2$ - 1.8 , for less basic pyridines to smaller values, $\rho_Z \cong 0.8$ for more basic pyridines, which is in agreement with the decrease in bond cleavage at the rate-determining step switches from breakdown to formation of the intermediate. Such decrease in the magnitude of the ρ_Z values from large ($\rho_Z = 2.4$ - 3.2) to small values ($\rho_Z = 2.3$) with the mechanistic change is also reported in the pyridinolysis of aryl dithioacetates.²² Rough estimate of the $\beta_Z (= \beta_{Z_2})$ values shows a decrease from $\beta_Z \cong -0.5$ to 0.3 at the breakpoint in agreement with the change in the rate-determining step.

Another important results that support mechanistic change at $pK_a^0 = 5.2$ from breakdown to formation of T^\pm as the basicity of pyridine is increased is a clear-cut change in the cross-interaction constant from a relatively large positive, $\rho_{NZ} = +1.36$, to a small negative value, $\rho_{NZ} = -0.22$, at the breakpoint. Similar changes of the ρ_{NZ} values have been reported for the pyridinolysis of S-phenyl 4-nitrobenzoates,²¹ 4- $NO_2C_6H_4C(=O)SC_6H_4Z$, and aryl dithioacetates,²⁴ $CH_3C(=S)SC_6H_4Z$. In the former the ρ_{NZ} value change from $+1.41$ to 0.32 at $pK_a^0 \cong 4.2$ and in the latter from $+1.34$ to -0.15 at $pK_a^0 = 5.2$ as the basicity of pyridine is increased. These are of course interpreted to indicate mechanistic changes from breakdown to formation of T^\mp . These changes in the ρ_{NZ} values with changes in the mechanism of reaction

Table 2. Activation Parameters^a for the Reactions of Z-Phenyl Dithiomethylacetates with X-Pyridines in Acetonitrile

X	Z	t (°C)	k _N (× 10 ³ M ⁻¹ s ⁻¹)	ΔH [‡] (kcal mol ⁻¹)	-ΔS [‡] (cal mol ⁻¹ K ⁻¹)
4-CH ₃ O	4-CH ₃	60.0	5.57	5.6	52
		50.0	4.09		
		40.0	3.04

		40.0	0.135		

^aCalculated by the Eyring equation. The maximum errors calculated (by the method of K. B. Wiberg, *Physical Organic Chemistry*, Wiley, New York, 1964, p 378.) are ± 0.6 kcal mol⁻¹ and ± 2 e.u. for ΔH[‡] and ΔS[‡], respectively.

provide further credence to the cross-interaction constant as a useful mechanistic criterion.

The activation parameters determined with the rate constants at three temperatures are shown in Table 2. The activation enthalpies are low (ΔH[‡] ≅ 6 kcal/mol), and activation entropies have large negative values (ΔS[‡] = -51 to -62 cal mol⁻¹ K⁻¹). The large negative ΔS[‡] values (from -58 to -62 cal mol⁻¹ K⁻¹) for the weakly basic pyridine (X = 3-Cl) are in accord with the rate-limiting expulsion of the leaving group since the soft ArS⁻ groups formed in the TS are solvated by the soft aprotic solvent (MeCN) molecules.

We have confirmed that the aminolysis of aryl dithiomethylacetates in acetonitrile proceeds by a stepwise mechanism through a zwitterionic tetrahedral intermediate, T⁻, with rate-limiting expulsion of the thiophenoxide (ArS⁻) group by observing the breakpoint at pK_a^o = 5.2 due to change in the rate-limiting step associated with the intermediate, T⁻. The relatively low pK_a^o value is ascribed to the stability of the tetrahedral intermediate where the decrease in k_{-a} is greater than that in k_b with Y = S relative to that with Y = O. The mechanistic change from rate-limiting expulsion of the leaving group from T[±] to formation of the intermediate is well defined by a change in the cross-interaction constants ρ_{NZ} from a large positive value (+1.36) to a small negative value (-0.22).

Experimental Section

Materials. Merk GR acetonitrile was used after three distillations. The pyridine nucleophiles, Aldrich GR, were used without further purification.

Substrates. Preparations and analytical data are reported elsewhere.¹⁵

Kinetic measurement. Rates were measured conductometrically in acetonitrile. The conductivity bridge used in this work was a homemade computer-automatic A/D con-

verter conductivity bridge. Pseudo-first-order rate constants, k_{obs}, were determined by the Guggenheim method with large excess of pyridine (Py). Second order rate constants, k₂, were obtained from the slope of a plot of k_{obs} vs [Py] with more than five concentrations of pyridine. The k₂ values in Table 1 are the averages of more than three runs and were reproducible to within ± 3%.

Product analysis. Substrate, p-bromophenyl dithiomethylacetate (0.05 mole) was reacted with excess 4-picoline (0.5 mole) with stirring for more than 15 half-lives at 60.0 °C in acetonitrile. The salt was filtered and solvent was removed from the precipitate. Analysis of the product gave the following results.

CH₃CH₂C(=S)N⁺C₅H₄-p-CH₃⁻SC₆H₄-4-Br: m.p. 58-61 °C, ¹H NMR (400 MHz, CDCl₃), 2.35 (3H, s, CH₃), 2.91 (1H, q, CH₂), 7.31-7.34 (4H, m, phenyl), 8.45-8.85 (4H, m, pyridine); ¹³C NMR (100.4 MHz, CDCl₃), 227.1 (C=S), 135.7, 135.1, 132.4, 132.1, 131.5, 129.4, 123.5, 122.9, 121.5, 26.1 (CH₃); ν_{max} (KBr), 1567, 1455 (C=C, phenyl), 1229 (C=S), 855 (C-H, pyridine), 801 (C-H, phenyl); mass, m/z 402 (M⁺). Anal. Calcd for C₁₉H₁₆BrNS₂: C, 56.7; H, 4.01. Found; C, 56.5; H, 4.03.
