# Synthesis of Novel 2,3-Dihydro-2-phenylquinolone Dimers Using $\beta$-Ketoester and $N$-Alkylaniline 

Ju-Hee Kim and Myung-Sook Park*<br>College of Pharmacy, Duksung Women's University, Seoul 132-714, Korea. 'E-mail: mspark@duksung.ac:kr Received February 8, 2006

Key Words: Qumolone dimer, 2,3-Dihydro-2-phenyl-4-quinolones, Syndhesis, Dimerization, Asymmetric dimer

New dimer, $N . N^{\prime}$-dialkyl-2,2', $4^{\prime}$-trihydroxy-4-oxo-2, $2^{\prime}, 3,3^{\prime}$ -tetrahydro-2,2'diphenyl-4,4'diquinolones were synthesized for the development of new candidates for anticancer drug through coupling of $N$-alkylanilines and ethyl benzoylacetate. $A$ series of dimers was synthesized using an acid-catalyred one-pot reaction involving condensation, cyelization, and dimerization. The formation of dimers was accomplished using $p$-toluencsulfonic acid ( $p$-TSA) at $90-110^{\circ} \mathrm{C}$ in toluene for $3.5-9 \mathrm{~h}$ in a Dean-Stark apparatus.
The $N$-alkylation of secondary amines with $\beta$-keto ester is not only important for the synthesis of tertiary amines, but is also essential for the preparation of a number of phamaceuticals. Many reports have been published on the N -mono and N.N-dialkylation of anilines. ${ }^{1-7}$ Even though synthetic pathways for 2-phenyl-4-quinolones were developed by Li et al., ${ }^{8}$ Kuo et al., ${ }^{4}$ Waterson et al., ${ }^{11}$ Xia et al., ${ }^{11}$ and for 2,3-dihydro-2-phenyl-4-quinolones by Park et al., ${ }^{12}$ the synthesis of the dimers of 2,3-dihydro-2-phenyl-4-quinolones has not been reported until now. We applied a general method of preparing amines from a secondary amine and ketones ${ }^{2}$ and a synthetic one-pot operation to produce dihydroquinotone, and previously described a catalytic method that allows the 2-phenylquinolones. ${ }^{12}$ 2-Phenylquinolones have been extensively studied as potential antitunor compound. ${ }^{13}$
In our continuing study on the application of 2,3-dihydro-2-phenyl-4-quinotones, we examined $N$-alkylanilines as
secondary amines in order to discover of novel compound and N -alkylanilines were effective to coupling with ethyl benroylacelate to give the corresponding dimers. Here, we present our results concerning the coupling of $N$-alkylated anilines by $\beta$ keto ester, which provide aceess to quinolone dimers.
$N$-Alkylated anilines 2 were synthesized from various anilines 1 through selective $N$-monoalkylation using alkyl halide and triethylamine. ${ }^{14}$ Quinolones 3a-n were prepared by coupling of $N$-alkylated anilines and elhyl benzoylacetate in toluene (Scheme 1).

We previously reported the synthesis of 2.3 -dihydro-2-phenyl-4-quinolone using primary aniline. ${ }^{2}$ The 2,3-dihydro-2-phenyl-4-quinolone derivatives were synthesized through dehydration, dealcoholation and hydration of related primary anilines and elhyl benzoylacetate. But we synthesized the dimers of quinolones without any monomer derivatives from related secondary anilines and ethyl benzoylacetate. In the formation of dimers, the monomers were not observed on the TLC monitoring. The proposed reaction mechanism for the formation of the linal product involves eyclization between $N$-alkylated anilines and ethyl benzoylacetate (EBA) and internolecular coupling between two quinolone molecules. When a $\beta$-keto ester is treated with a secondary amine in the presence of catalyst, reductive alkylation of the amine takes place to produce the ester intermediate. Ester was continuously converted to the appropriate quinolone by the removal of ethanol. The internolecular reaction

Scheme 2. Proposed mechanism for dimer formation; compound 3a-n.
appeared dependent on the nueleophilic properties of the 3position. We thought that $N$-alkylaniline added to the $\beta$ ketoester to form a dipolar tetrahedral intermediate and proton transfer from nitrogen to oxygen produced a hemiaminal and the dimers were prepared through dealcoholation and rapid additional nucleophillic reaction of $a$-carbon to $4^{\text {t- }}$ position of another molecule (Scheme 2).

The $p$-toluenesulfonic acid ( $p$-TSA) assisted coupling of various N-methyl (or ethyl) anilines and EBA, resulting in cyclization and dimerization. A typical reaction is deseribed as follows. A mixture of N -alkylaniline ( 11 mmol ), EBA ( 10 mmol) and $p$-TSA ( 0.1 mmol ) in anhydrous toluene was stirred under reflux for $3.5-9 \mathrm{~h}$ in a Dean-Stark apparatus. The reaction was carried out using $1: 1.1$ equivalents of T:BA/N-alkylanilines. The moicties introduced to the aromatic nucleus of quinolones $\mathbf{3 a - n}$ were 6 -methyl, 7 methyl, 6-cthyl, 7-ethyl, 8-ethyl, 6-acetoxy, 7-acetoxy, 6ethoxy, and 7-cthoxy.
E:BA and $N$-methyl (or ethyl)-4(or 3)-toluidines and $N$ methyl (or ethyl)-3(or 2)-ethylanilines were reacted with $p$ TSA in toluene to form the corresponding dimer products in good yields. Similarly, $N$-methyl (or ethyl)-4(or 3)-phenetidines and N -methyl-4(or 3 )-aminoacetophenones were converted into dimers in somewhat lower yields.
Product 3a-n were identified by NMR, IR and FABMS. The 3-CH nmr peak of $\mathbf{3 a - n}$ appeared at $5.13-5.45 \mathrm{ppm}$, and the $3^{\prime}-\mathrm{CH}_{2}$ peak at $3.85-3.88 \mathrm{ppm}$. The ${ }^{13} \mathrm{C}$ nmr peak of 4 carbonyl appeared at 194 ppm , the 3-CH peak at 86.3387.68 ppm . and $3^{\prime}-\mathrm{CH}_{2}$ peak at $44.03-46.54$ ppm. Final products 3a-n produced a monomer fragnent in the MS spectra.
In conclusion, the combination of $N$-alkylated aniline/ EBA $p$-TSA was found to provide a convenient method for giving dimerized quinolones in satisfactory yields. The dimers of 2,3-dihydro-2-phenyl-4-quinolone 3a-n were synthesized by condensation, cyclization, and nucleophilic reaction of $N$-substituted anilines with ethyl benzoylacetate in order to discover antitumor candidates.

## Experimental Section

Chemicals were supplied by Aldrich, Sigma, Merck, and Tokyo Kasei. Melting points were determined in open
capillary tubes on a Büchi 535 melting point apparatus and uncorrected. The NMR spectra were recorded using a Bruker $300 \mathrm{MH} \%$ NMR spectrometer. Chemical shift values were reported in parts per million scales in deuteriochlowoform or dimethyl-d $d_{6}$ sulfoxide with tetramethylsilane as the intemal standard. The NMR spin multiplicities were indicated by the symbols: $s$ (singlet), $d$ (doublet), $t$ (triplet), $q$ (quartet) and m (multiplet). IR spectra were recorded on a Perkin-Elmer FTIR spectrometer using NaCl dises and pellets. Iow and highresolution TABMS (positive ion mode) mass spectra were determined on a JTOI. 700 mass speetrometer.

General Procedure for the compounds 3a-n. Tthyl benzoylacetate ( $2.76 \mathrm{~mL}, 16 \mathrm{mmol}$ ), $p$-toluenesulfonic acid $(38.0 \mathrm{mg}, 0.2 \mathrm{mmol})$ and $N$-methyl- $p$-koludine $2(2.52 \mathrm{~mL}, 20$ momol) were relluxed for about 6.5 h in anhydrous toluene ( 35 mL ) over the Dean-Stark apparatus until the starting material disappeared. The reaction mixture was allowed to cool to romm temperature, concentrated under reduced pressure to remove the toluene. The residue was extracted with ethyl acetate ( 30 mL ) and water ( $15 \mathrm{~mL} \times 3$ ). The extracts were dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$, and concentrated under a reduced pressure. The residue was purified by column chromategraphy ( $\mathrm{SiO}_{2}, n$-hexane : ethyl acetate) to give compound 3a as high viscous oil. The oil was crystallized from methanol.
