Purpose: Since a patient's obesity can affect the mortality and morbidity of the surgery, less drastic surgeries may have a major benefit for obese individuals. This study evaluated the feasibility of performing a totally laparoscopic distal gastrectomy, with intracorporeal anastomosis, in obese patients suffering from gastric cancer.

Materials and Methods: This was a retrospective analysis of the 138 patients, who underwent a totally laparoscopic distal gastrectomy from April 2005 to March 2009, at the National Kyushu Cancer Center. The body mass index of 20 patients was ≥ 25 , and in 118 patients, it was < 25 kg/m².

Results: The mean values of body mass index in the 2 groups were 27.3 ± 2.2 and 21.4 ± 2.3 . Hypertension was significantly more frequent in the obese patients than in the non-obese patients. The intraoperative blood loss, duration of surgery, post-operative complication rate, post-operative hospital stay, and a number of retrieved lymph nodes were not significantly different between the two groups.

Conclusions: Intracorporeal anastomosis seemed to have a benefit for obese individuals. Totally laparoscopic gastrectomy is, therefore, considered to be a safe and an effective modality for obese patients.

Key Words: Laparoscopy; Gastrectomy; Stomach neoplasms; Obesity; Body mass index

Introduction

In Japan, laparoscopy-assisted gastrectomy and lymph node dissection with curative intent have been recommended and practiced for the treatment of early gastric cancers since the first report in 1994 of a laparoscopy-assisted distal gastrectomy (LADG) with a Billroth I anastomosis for a patient with gastric cancer.⁽¹⁾ Obesity is associated with the mortality and morbidity of a gastrectomy in open surgery.⁽²⁻⁵⁾ Obesity might increase the rate of intra-

operative or post-operative complications. Therefore, less invasive surgery, such as an LADG, may have a greater impact in the obese patients by reducing the rate of complications, length of the hospital stay, and permitting a more rapid return to physical activities. There have been a few studies that have investigated the impact of obesity on laparoscopy-assisted distal gastrectomy.⁽⁶⁻⁸⁾ These reports have shown technical difficulties and a longer duration of surgery in the obese patients.

A totally laparoscopic distal gastrectomy (TLDG) is defined as a method used to perform both the resection and anastomosis intracorporeally with a laparoscopic technique. TLDG has several advantages over LADG including smaller wounds, less invasiveness, and a greater chance of a secure ablation.⁽⁹⁾ However, the introduction of TLDG for all people still remains controversial, since it is generally believed that the time required for a TLDG is longer and the surgical procedure is more difficult than for a LADG. study compared the factors associated with the outcome of a TLGD in obese patients and non-obese patients to elucidate the safety and advantages for the obese patients.

Materials and Methods

1. Patients

One hundred thirty-eight patients underwent a TLGD for gastric cancer in the National Kyushu Cancer Center in Japan between April 2005 and March 2009. A TLGD was performed in patients with T1N0M0 and T2N0M0 gastric cancer regardless of their gender, age, body mass index (BMI) or comorbidities. The patients were divided into two groups, consisting of obese and non-obese patients, according to the obesity criteria recommended by the Japan Society of Obesity. The BMI in the non-obese group was <25.0 (n=118); in the obese group, the BMI was ≥ 25.0 (n=20). The

concurrent diseases, duration of surgery, blood loss, hospital stay and post-operative morbidity were compared in the two groups. Information was collected from the medical records and anesthesia records including age, gender, duration of surgery, estimated blood loss, blood test data, lung function tests, pathological findings and post-operative complications or parenteral nutritional support.

2. Surgical procedures

The distal gastrectomy and lymph node dissection were performed according to the guideline of the Japanese Gastric Cancer Association.(10) The patient was placed under general anesthesia in the supine position. A 12-mm trocar was inserted in the umbilical region using a cut-down method. A laparoscope was inserted through the trocar and the liver was pulled up using a Penrose drain and a J-shaped retractor.(11) The detailed surgical procedure of the TLGD was reported previously.(9,11) The distal stomach

Table 1. Clinicopathologic characteristics of patients who underwent totally laparoscopic distal gastrectomy

Characteristic		BMI ≥ 25 (n=20)	BMI<25 (n=118)	P-value
Mean age (yr)		63.5 \pm 11.1	63.4 \pm 11.2	0.845
Gender	M	12 (60)	63 (53.4)	0.583
	F	8 (40)	55 (46.6)	
BMI		27.3 \pm 2.2	21.4 \pm 2.3	<0.001
VC		3,223.2 \pm 865.2	3,310 \pm 825.4	0.729
%FEV*		75.1 \pm 9.6	76.0 \pm 9.6	0.918

	Cardiovascular disease	2 (10.0)	10 (8.5)	0.822
	Diabetes mellitus	4 (20.0)	13 (11.0)	0.258
	Liver disease	0	6 (5.1)	0.302
Operation history		2 (10.0)	6 (5.1)	0.933

Values are presented as mean \pm standard deviation or n (%). BMI = body mass index; M = male; F = female; VC = vital capacity. *The ratio of the forced expiratory volume in one second. [†]American Society of Anesthesiologists physical status.

was removed and reconstructed using the Billroth I or Roux-en Y method. Billroth I reconstruction was performed with a delta-shaped anastomosis(12) and Roux-en Y reconstruction was also performed using a linear stapler.(13) Both anastomoses were completed intracorporeally.

3. Definitions of complications

Intraoperative complications were defined as conditions that required either an open conversion or additional procedures to the planned surgery for any reason. Post-operative minor complications were defined as any abdominal finding during the post-operative course not requiring medication or a systemic complication requiring pharmacologic treatment. Major post-operative complications were defined as any complication requiring surgical or radiological intervention.

4. Statistical analysis

The statistical analysis was performed using the JMP 7 software package (SAS Institute Inc., Cary, NC, USA). All values are expressed as the means \pm standard deviation. The Chi-square test and Fisher's exact test were used for the statistical analysis.

Table 2. Surgical outcomes of totally laparoscopic distal gastrectomy

Characteristic	BMI \geq 25 (n=20)	BMI<25 (n=118)	P-value
Operation time (min)	321.9 \pm 61.6	322.0 \pm 74.7	0.79
Estimated blood loss (g)	146.5 \pm 189.7	114.6 \pm 130.6	0.60
Time to resumed oral intake (d)	3.55 \pm 1.09	3.42 \pm 0.94	0.92
Retrieved lymph nodes	30.8 \pm 16.2	32.7 \pm 15.0	0.43
CRP (mg/dl)*	4.01 \pm 3.50	3.50 \pm 4.18	0.21
Post-operative hospital stay (d)	14.4 \pm 4.8	16.6 \pm 16.4	0.88

Values are presented as mean \pm standard deviation. BMI = body mass index; CRP = C-reactive protein. *7 days after operation.

Table 3. Intra-operative complications

Characteristic	BMI \geq 25 (n=20)	BMI<25 (n=118)	P-value
Open conversion	1 (5.0)	1 (0.8)	
Bleeding	1 (5.0)	7 (5.9)	
Re-anastomosis	0	1 (0.8)	
Total	1 (5.0)	8 (6.8)	0.767

Values are presented as n (%). BMI = body mass index.

Results

1. Clinicopathological findings

The characteristics of the 138 patients are summarized in Table 1. The mean values of BMI in the 2 groups were 27.3 \pm 2.2 and 21.4 \pm 2.3, respectively, for obese and non-obese patients. The gender and age, stage of gastric cancer, extent of lymph node dissection and type of reconstruction were not significantly different between the two groups. In addition, the vital capacity and the ratio of the forced expiratory volume in one second, the hemoglobin and the albumin levels were not significantly different in two groups. A severe comorbidity (American Society of Anesthesiologists class 3) was present in 11 patients in the non-obese group and one patient in the obese group. Table 1 shows the pre-operative concurrent diseases in both groups. The most frequent concurrent disease in both groups was hypertension, and the incidence of hypertension was significantly more frequent in the obese patients than in the non-obese patients.

2. Surgical and peri-operative outcomes and post-operative complications

No significant differences were observed regarding the operation time, estimated blood loss, number of retrieved lymph nodes,

Table 4. Post-operative complications

Characteristic	BMI \geq 25 (n=20)	BMI<25 (n=118)	P-value
Minor complication			
Wound infection	1 (5.0)	10 (8.5)	0.574
Cholecystitis	0	1 (0.8)	0.575
Leakage of lymph	0	1 (0.8)	0.575
Arrhythmia	0	1 (0.8)	0.575
Delirium	1 (5.0)	0	0.048
Total	2 (10.0)	13* (11.0)	0.892
Major complication			
Leakage or intra-abdominal fluid collection	0	3 (2.5)	0.329
Leakage of pancreatic juice	0	3 (2.5)	0.329
Liver infarction	0	1 (0.8)	0.575
Colon injury	0	1 (0.8)	0.575
Anastomosis bleeding	0	1 (0.8)	0.575
Ileus	0	3 (2.5)	0.329
Total	0	12* (10.2)	0.135

Values are presented as n (%). BMI = body mass index. *Duplicated cases were included.

Table 5. Multivariate analysis of complications for high BMI

Complication	P-value	OR	95%CI
Open conversion	0.137	13.3	-3.259~0.5134
Bleeding	0.605	0.484	-5,138.4~5,090.5
Wound infection	0.381	0.323	0.423~107.29
Leakage of pancreatic juice	0.995	3.02E-07	-1.090~2904.5
Leakage or intraabdominal fluid collection	0.996	4.11E-07	-2,872.4~2,887.1
Ileus	0.996	1.78E-07	-3,069.8~3,085.4

BMI = body mass index; OR = odds ratio; CI = confidence interval.

the value of C-reactive protein 7 days after the operation and post-operative hospital stay (Table 2) between the two groups. Table 3 and 4 summarize the peri-operative complications in univariate analysis. Each group had one conversion case from a laparoscopic gastrectomy to an open gastrectomy. Unexpected bleeding occurred in 8 cases. Post-operative complications were categorized into minor or major complications. No significant differences were noted between the two groups in the incidence of major complications such as anastomotic leakage, anastomotic bleeding and colon injury. Six major factors associated with peri- or post-operative complications were selected for the multivariate analysis. None of the factors significantly increased in the high BMI cases (Table 5).

Discussion

A laparoscopic distal gastrectomy (LDG) is generally used for the treatment of gastric cancer, since this type of surgery has demonstrated benefits over open surgery.(1,14) Many surgeons expected that the laparoscopic approach for gastric surgery would improve the morbidity and mortality for high risk patients in comparison to open surgery. However, the advantages for high risk patients, such as the obese, elderly and patients with low respiratory function are still controversial. Some previous studies have suggested that there is no difference in the post-operative morbidity and mortality between obese and non-obese patients associated with LDG for gastric cancer.(6-8,15,16) However, a longer duration of surgery and more difficult operations have been reported for obese patients.(7,8)

Recently, a TLDG has been used for the treatment of gastric cancer.(9,17,18) TLDG is a method in which both the resection and anastomosis are performed intracorporeally using laparoscopic procedures. Previous studies have shown favorable results with TLDG and demonstrated this approach with lymph node dissection

to be technically feasible, and it is thus considered to be an effective surgical modality for gastric cancer without a high morbidity rate. In this report, we retrospectively compared the factors associated with the outcome of a TLDG in obese patients and non-obese patients to elucidate the safety and advantages for the obese patients. We found no significant differences between the two groups in terms of the duration of surgery, bleeding and post-operative complications.

The most important problem resulting from the laparoscopic surgery for obese patient was anastomosis. The anastomosis is performed in the abdominal cavity in TLDG, and excessive torsion is not applied to the remnant stomach and duodenum. Therefore, no extension of the wound or minilaparotomy is usually necessary. This made the anastomosis simple and easy. Therefore, anastomosis-related complications are rarely observed. Wound infections may be more frequent in obese patients.(19,20) The risk for wound infection also decreases following the TLDG procedure because of the smaller wound.

In open surgery, it has been reported that the number of retrieved lymph nodes for gastrectomy with D2 resection was not affected by obesity.(21) On the other hand, another report showed that the number of examined lymph nodes was affected by obesity.(22) Laparoscopic surgery has advantages for minute surgical procedures, such as lymph node dissection, however it is controversial whether the number of retrieved lymph nodes is influenced by obesity or not when using this procedure.(6,15) In our investigation, the duration of surgery and the number of retrieved lymph nodes was not different between obese and non-obese patients. The average number of retrieved lymph nodes in obese patients was 30.8 ± 16.2 and that in non obese patients were 32.7 ± 15.0 . Laparoscopic surgery therefore seems to be more suitable for lymph node dissection because of the magnification of the field of vision, even for obese patients.

In conclusion, the TLDG is therefore considered to be a safe and effective procedure for obese patients since there were no differences in the duration of surgery, estimated blood loss, and rate of complications, in spite of the difference in the patients' background. This method can therefore be recommended as a standard treatment for obese patients.
