# MULTI-PARAMETERIZED SCHWARZ ALTERNATING METHOD FOR 3D-PROBLEM ${ }^{\dagger}$ 

SANG-BAE KIM

#### Abstract

The convergence rate of a numerical procedure based on Schwarz Alternating Method(SAM) for solving elliptic boundary value problems depends on the selection of the interface conditions applied on the interior boundaries of the overlapping subdomains. It has been observed that the Robin condition (mixed interface condition), controlled by a parameter, can optimize SAM's convergence rate. In [7], one formulated the multi-parameterized $S A M$ and determined the optimal values of the multi-parameters to produce the best convergence rate for one-dimensional elliptic boundary value problems. Two-dimensional implementation was presented in [8]. In this paper, we present an implementation for threedimensional problem.

AMS Mathematics Subject Classification : 65N35, 65N05, 65F10.
Key words and phrases : elliptic partial differential equations, Schwarz alternating method, Jacobi iterative methods.

## 1. Introduction

Schwarz-type alternating methods have become some of the most important approaches in domain decomposition techniques for solution of the boundary value problems (BVP's). These methods are based on a decomposition of the BVP domain into overlapping subdomains. The original BVP is reduced to a set of smaller BVP's on a number of subdomains with appropriate interface conditions on the interior boundaries of the overlapping areas, whose solutions are coupled through some iterative scheme to produce an approximation of the solution of the original BVP. It is known [1], [6] that under certain conditions the sequence of the solutions of the subproblems converges to the solution of the original problem.

One of the objectives of this research is to study a class of Schwarz alternating methods (SAM's) whose interface conditions are parameterized and estimate the

[^0]values of the parameters involved that speed up the convergence of these methods for a class of BVP's. In the context of elliptic BVP's the most commonly used interface conditions are of Dirichlet type. For this class of numerical SAM, there are several studies about the convergence, which include [10], [12], [15], [16], [13], [2], [11], [17]. The effect of parameterized mixed interface conditions has been considered by a number of researchers [3], [14], [5], [18]. Among them, Tang proposed a generalized Schwarz splitting [18]. The main part of his approach to the solution of a BVP is to use the mixed boundary condition, known as Robin condition,
\[

$$
\begin{equation*}
B(u)=\omega u+(1-\omega) \frac{\partial u}{\partial n} \tag{1}
\end{equation*}
$$

\]

on the artificial boundaries. In [5], a multi-parameter SAM is formulated in which the mixed boundary conditions

$$
\begin{equation*}
B_{i}(u)=\omega_{i} u+\left(1-\omega_{i}\right) \frac{\partial u}{\partial n} \tag{2}
\end{equation*}
$$

are controlled by a distinct parameter $\omega_{i}$ for the $i$-th overlapping area. Fourier analysis is applied to determine the values of $\omega_{i}$ parameters that make the convergence factor of SAM be zero.

In [7], one formulated a multi-parameter SAM at the matrix level where the parameters $\alpha_{i}$ are used to impose mixed interface conditions. The relation between the parameters $\alpha_{i}$ and $\omega_{i}$ is given by

$$
\begin{equation*}
\alpha_{i}=\frac{1-\omega_{i}}{1-\omega_{i}+\omega_{i} h} \tag{3}
\end{equation*}
$$

(Refer to [7]), where $h$ is the grid size. One determined analytically the optimal values of $\alpha_{i}$ 's for one-dimensional(1-dim) boundary value problems, which minimize the spectral radius of the block Jacobi iteration matrix associated with the SAM matrix.

For two-dimensional (2-dim) boundary value problems [8], we used distinct multi-parameter $\alpha_{i, j}$ for each $j$-th grid point of the $i$-th interfaces of the subdomains to get the best convergence, while we used a fixed parameter $\alpha_{i}$ along the $i$-th interfaces of the subdomains in the previous paper [7].

In this paper, we consider the case of three-dimensional (3-dim) problem. Here we also use distinct multi-parameter $\alpha_{i, j, k}$ for each $(j, k)$-th grid point of the $i$-th interfaces of the subdomains to get sucessfully the best convergence.

In section 2, we summarize the result of the multi-parameterized SAM on 1dim problem, which has been presented in [7] and is nessary for notations in the following section. In section 3, we formulate the multi-parameterized SAM on 3-dim problem where we impose distinct parameters on each grid point on the interfaces of the subdomains. We show that the 3 -dim case can be reduced to the one-dimensional ones and obtain the optimal values of the multi-parameters which minimize the spectral radius of the block Jacobi iteration matrix associated with the SAM matrix of 3 -dim problem.

Figure 1. An example of the $\kappa$-way decomposition of the domain of one dimensional boundary value problem (4).

## 2. Multi-Parameterized Schwarz Splitting for 1-dim problem

We consider the two-point boundary value problem:

$$
\begin{gather*}
-u^{\prime \prime}(t)+q u(t)=f(t), t \in(0,1) \\
u(0)=a_{0}, u(1)=a_{1} \tag{4}
\end{gather*}
$$

with $q \geq 0$ being a constant. We will formulate a numerical instance of SAM based on a $\kappa$-way decomposition (i.e. the number of subdomains is $\kappa$ ) of the problem domain. An example of $\kappa$-way decomposition is depicted in Figure 1.

Let $T_{j}(x, y, z)$ be a $j \times j$ tridiagonal matrix such that

$$
T_{j}(x, y, z)=\left[\begin{array}{ccccc}
x & -1 & 0 & \cdots & 0  \tag{5}\\
-1 & y & -1 & \cdots & 0 \\
\vdots & \ddots & \ddots & \ddots & \vdots \\
0 & \cdots & -1 & y & -1 \\
0 & \cdots & 0 & -1 & z
\end{array}\right]
$$

and let

$$
\begin{equation*}
T_{j}(x) \equiv T_{j}(x, x, x) \tag{6}
\end{equation*}
$$

If we discretize the problem (4) by a second order central divided difference discretization scheme with a uniform grid of mesh size $h=\frac{1}{n+1}$, we obtain a linear system

$$
\begin{equation*}
A x=f \tag{7}
\end{equation*}
$$

where $A=T_{n}(\beta)$ with $\beta=2+q h^{2}$.
If we consider 3-way $(\kappa=3)$ decomposition, then $A x=f$ has three overlapping diagonal blocks as follows.
$\left[\begin{array}{ccccc}\hline T_{m-l} & -F & 0 & 0 & 0 \\ -E & T_{l} & -F & 0 & 0 \\\right.$\cline { 2 - 5 } 0 \& $-E & T_{m-2 l} & -F & 0 \\$\cline { 2 - 5 } 0 \& 0 \& $\left.-E & T_{l} & -F \\ 0 & 0 & 0 & -E & T_{m-l}\end{array}\right]\left[\begin{array}{c}x_{1} \\ x_{2} \\ x_{3} \\ x_{4} \\ x_{5}\end{array}\right]=\left[\begin{array}{c}f_{1} \\ f_{2} \\ f_{3} \\ f_{4} \\ f_{5}\end{array}\right]$
where $T_{j}=T_{j}(\beta, \beta, \beta)$ in (5) and $m$ and $l$ are the numbers of nodes in each subdomain and the overlapping regions, respectively, such that $l<\frac{m-1}{2}$. In (8), the matrix $E$ have zero elements everywhere except for a 1 at the rightmost top position and the matrix $F$ have zero elements everywhere except for a 1 at the
leftmost bottom position. So the matrices $E$ and $F$ have compatible sizes with the following forms.

$$
E=\left[\begin{array}{cccc}
0 & \cdots & 0 & 1  \tag{9}\\
0 & \cdots & 0 & 0 \\
\vdots & & \vdots & \vdots \\
0 & \cdots & 0 & 0
\end{array}\right], F=\left[\begin{array}{cccc}
0 & 0 & \cdots & 0 \\
\vdots & \vdots & & \vdots \\
0 & 0 & \cdots & 0 \\
1 & 0 & \cdots & 0
\end{array}\right]
$$

The numerical version of SAM [17] for the problem (4) is equivalent to a block Gauss-Seidel iteration procedure for a new linear system, called Schwarz Enhanced Matrix Equation,

$$
\begin{equation*}
\tilde{A} \tilde{x}=\tilde{f} \tag{10}
\end{equation*}
$$

where

$$
\tilde{A}=\tilde{A}(\beta)=\left[\begin{array}{ccccccc}
\hline T_{m-l} & -F & 0 & 0 & 0 & 0 & 0  \tag{11}\\
-E & T_{l} & 0 & -F & 0 & 0 & 0 \\
\hline-E & 0 & T_{l} & -F & 0 & 0 & 0 \\
0 & 0 & -E & T_{m-2 l} & -F & 0 & 0 \\
0 & 0 & 0 & -E & T_{l} & 0 & -F \\
0 & 0 & 0 & -E & 0 & T_{l} & -F \\
0 & 0 & 0 & 0 & 0 & -E & T_{m-l}
\end{array}\right], \tilde{x}=\left[\begin{array}{l}
x_{1} \\
x_{2} \\
x_{2}^{\prime} \\
x_{3} \\
x_{4} \\
x_{4}^{\prime} \\
x_{5}
\end{array}\right], \tilde{f}=\left[\begin{array}{l}
f_{1} \\
f_{2} \\
f_{2} \\
f_{3} \\
f_{4} \\
f_{4} \\
f_{5}
\end{array}\right] .
$$

$\tilde{A}(\beta)$ means that $\tilde{A}$ is a function of $\beta$. Note that the solution $x$ of (7) is obtained from the solution $\tilde{x}$ of (10), vice versa. In [18], it is shown that a good choice of the splitting of $T_{l}$ 's can significantly improve the convergence of SAM. Applying for some splittings of $T_{l}$ 's into $\tilde{A}$ in (11), we have a new equation

$$
\begin{equation*}
A^{\prime} \tilde{x}=\tilde{f} \tag{12}
\end{equation*}
$$

with

$$
A^{\prime}=A^{\prime}\left(\beta, \alpha_{1}, \alpha_{2}\right)=\left[\begin{array}{cc|ccccc}
\hline T_{m-l} & -F & 0 & 0 & 0 & 0 & 0  \tag{13}\\
-E & B_{1} & C_{1} & -F & 0 & 0 & 0 \\
\hline-E & C_{1}^{\prime} & B_{1}^{\prime} & -F & 0 & 0 & 0 \\
0 & 0 & -E & T_{m-2 l} & -F & 0 & 0 \\
0 & 0 & 0 & -E & B_{2} & C_{2} & -F \\
0 & 0 & 0 & -E & C_{2}^{\prime} & B_{2}^{\prime} & -F \\
0 & 0 & 0 & 0 & 0 & -E & T_{m-l}
\end{array}\right]
$$

where $B_{i}, C_{i}^{\prime}, i=1,2$ are some matrices such that $\left(B_{i}-C_{i}^{\prime}\right)$ is non-singular and

$$
\begin{equation*}
T_{l}=B_{i}+C_{i}=B_{i}^{\prime}+C_{i}^{\prime}, \quad i=1,2 \tag{14}
\end{equation*}
$$

Note that two linear system (10) and (12) are equivalent in the sense that they have the same solutions. If $C_{i}^{\prime}$ and $C_{i}$ are chosen such that they are the $l \times l$ matrices with all zero entries except for an $\alpha_{i}$ in the positions $(1,1)$ and $(l, l)$, respectively, as follows,

$$
C_{i}^{\prime}=\left[\begin{array}{cccc}
\alpha_{i} & 0 & \cdots & 0  \tag{15}\\
0 & 0 & \cdots & 0 \\
\vdots & \vdots & & \vdots \\
0 & 0 & \cdots & 0
\end{array}\right], C_{i}=\left[\begin{array}{cccc}
0 & \cdots & 0 & 0 \\
\vdots & & \vdots & \vdots \\
0 & \cdots & 0 & 0 \\
0 & \cdots & 0 & \alpha_{i}
\end{array}\right]
$$

the resulting matrix $A^{\prime}$ is given as follows

$$
A^{\prime}=A^{\prime}\left(\beta, \alpha_{1}, \alpha_{2}\right)=\left[\begin{array}{ccc}
T_{m}\left(\beta, \beta, \beta-\alpha_{1}\right) & -F_{1}{ }^{\prime} & 0  \tag{16}\\
-E_{1}{ }^{\prime} & T_{m}\left(\beta-\alpha_{1}, \beta, \beta-\alpha_{2}\right) & -F_{2}{ }^{\prime} \\
0 & & -E_{2}{ }^{\prime} \\
T_{m}\left(\beta-\alpha_{2}, \beta, \beta\right)
\end{array}\right]
$$

where $T_{m}(x, y, z)$ 's are $m \times m$ matrices defined in (5) and $E_{i}{ }^{\prime}$ 's are the $m \times m$ matrices with zero elements everywhere except that

$$
\begin{aligned}
& (1, m-l) \text {-th entry }=1 \\
& (1, m-l+1) \text {-th entry }=-\alpha_{i}
\end{aligned}
$$

and $F_{i}{ }^{\prime}$ 's are the $m \times m$ matrices with zero elements everywhere except that

$$
\begin{aligned}
& (m, l+1) \text {-th entry }=1, \\
& (m, l) \text {-th entry }=-\alpha_{i} .
\end{aligned}
$$

If the number of subdomains $\kappa$ is more than 3 , the matrix $A^{\prime}$ is a block $\kappa \times \kappa$ matrix of the form

$$
A^{\prime}=A^{\prime}(\beta, \mathbf{a})=\left[\begin{array}{cccccc}
G_{1} & -F_{1}^{\prime}{ }^{\prime} & 0 & 0 & \cdots & 0  \tag{17}\\
-E_{1}^{\prime} & G_{2} & -F_{2}^{\prime} & 0 & \cdots & 0 \\
\vdots & & \ddots & \ddots & \ddots & \vdots \\
0 & \cdots & 0 & -E_{\kappa-2}^{\prime} & G_{\kappa-1} & -F_{\kappa-1}^{\prime} \\
0 & \cdots & 0 & 0 & -E_{\kappa-1}^{\prime} & G_{\kappa}
\end{array}\right]
$$

where $\mathbf{a}=\left(\alpha_{0}, \alpha_{1}, \alpha_{2}, \cdots, \alpha_{\kappa}\right)$ with $\alpha_{0}=\alpha_{\kappa}=0$ and $G_{i}$ 's are defined as

$$
\begin{equation*}
G_{i}=T_{m}\left(\beta-\alpha_{i-1}, \beta, \beta-\alpha_{i}\right), i=1,2, \cdots, \kappa . \tag{18}
\end{equation*}
$$

We call the matrix $A^{\prime}$ as Multi-Parameterized Enhanced Matrix. If we define

$$
M=M(\beta, \mathbf{a})=\left[\begin{array}{cccc}
G_{1} & 0 & \cdots & 0  \tag{19}\\
0 & G_{2} & \cdots & 0 \\
\vdots & & \ddots & \vdots \\
0 & \cdots & 0 & G_{\kappa}
\end{array}\right] \text { and } N=N(\beta, \mathbf{a})=\left[\begin{array}{cccccc}
0 & F_{1}{ }^{\prime} & 0 & 0 & \cdots & 0 \\
E_{1} & 0 & F_{2}{ }^{\prime} & 0 & \cdots & 0 \\
\vdots & & \ddots & \ddots & \ddots & \vdots \\
0 & \cdots & 0 & E_{\kappa-2}^{\prime} & 0 & F_{\kappa-1}^{\prime} \\
0 & \cdots & 0 & 0 & E_{\kappa-1}^{\prime} & 0
\end{array}\right]
$$

with $\mathbf{a}=\left(\alpha_{0}, \alpha_{1}, \alpha_{2}, \cdots, \alpha_{\kappa}\right)$, then we can write the multi-parameterized enhanced matrix $A^{\prime}$ as

$$
\begin{equation*}
A^{\prime}=M-N \tag{20}
\end{equation*}
$$

which is called a Multi-Parameterized Schwarz Splitting (MPSS).
The convergence behavior of MPSS depends on the spectral radius of the following block Jacobi matrix

$$
J=M^{-1} N=\left[\begin{array}{cccccc}
0 & G_{1}^{-1} F_{1}^{\prime} & 0 & 0 & \cdots & 0  \tag{21}\\
G_{2}^{-1} E_{1}{ }^{\prime} & 0 & G^{-1} F_{2}{ }^{\prime} & 0 & \cdots & 0 \\
0 & G_{3}^{-1} E_{2}^{\prime}{ }^{\prime} & 0 & G_{3}^{-1} F_{3}{ }^{\prime} & \cdots & 0 \\
\vdots & & \ddots & \ddots & \ddots & \vdots \\
0 & \cdots & 0 & G_{\kappa}-1 E_{\kappa-2}{ }^{\prime} & 0 & G_{\kappa}{ }^{-1}-1 F_{\kappa-1}{ }^{\prime} \\
0 & \cdots & 0 & 0 & G_{\kappa}{ }^{-1} E_{\kappa-1}{ }^{\prime} & 0
\end{array}\right] .
$$

Note that $J$ is a function of the parameters $\alpha_{i}$ 's, which correspond to the parameters $\omega_{i}$ 's in the mixed interface condition (2), respectively. The convergence

Figure 2. A 3 -way splitting of the unit cube $\Omega$.
rate of SAM can be optimized by controlling these parameters $\alpha_{i}$ 's. In [7], one determined the optimal values of the multi-parameter $\alpha_{i}$ 's that make the spectral radius of the block Jacobi matrix $J$ in (21) to be zero. The result of [7] is presented in the following theorem.
Theorem 2.1. Let $\theta=\cosh ^{-1}\left(\frac{\beta}{2}\right)$ with $\beta=2+q h^{2}$ and let $p \in\{1,2, \cdots, \kappa-1\}$ and let

$$
\Theta(x) \equiv \begin{cases}\sinh (x \theta), & \theta>0 \\ x, & \theta=0\end{cases}
$$

If the values $\alpha_{i}, i=0,1, \cdots, \kappa$, are given by

$$
\begin{aligned}
& \alpha_{0}=\alpha_{\kappa}=0 \\
& \alpha_{i}=\frac{\Theta(m-l)-\alpha_{i-1} \Theta(m-l-1)}{\Theta(m-l+1)-\alpha_{i-1} \Theta(m-l)}, \quad i=1,2, \cdots, p \\
& \alpha_{i}=\frac{\Theta(m-l)-\alpha_{i+1} \Theta(m-l-1)}{\Theta(m-l+1)-\alpha_{i+1} \Theta(m-l)}, \quad i=p+1, \cdots, \kappa-1
\end{aligned}
$$

then the spectral radius of the block Jacobi matrix $J$ in (21) is zero.

## 3. Multi-Parameterized Schwarz Splitting for 3-dim Problem

Consider the three-dimensional boundary value problem

$$
\begin{gather*}
-\nabla^{2} u(x)+q u(x)=f(x), \quad x \in \Omega, \\
u(x)=g(x), \quad x \in \Gamma \tag{22}
\end{gather*}
$$

where $\Gamma$ is the boundary of $\Omega \equiv(0,1) \times(0,1) \times(0,1)$ and $q \geq 0$ is a constant. We formulate a SAM based on a $\kappa$-way splitting of the domain $\Omega$, i.e., we decompose our domain into $\kappa$ overlapping subdomains $\Omega_{i}$ along the $x_{1}$-axis and make a strip-type decomposition of the cube domain $\Omega$ (for instance, see Figure 2). Next we apply the interface conditions on the two interior boundaries between subdomains $\Omega_{i}$ and $\Omega_{i+1}$. Let $\ell$ be the length of the overlap in $x_{1}$-direction and
$\eta$ be the length of each subdomain in the same direction. Figure 2 depicts such a 3 -way splitting of the unit cube $\Omega$.

To begin our analysis we use a 7 -point finite difference discretization scheme with uniform grid of mesh size $h=\frac{1}{n+1}$ on all of $x_{1^{-}}, x_{2^{-}}$and $x_{3}$-axes and discretize the BVP in (22) to obtain a linear system of the form

$$
\begin{equation*}
B x=f \tag{23}
\end{equation*}
$$

The natural ordering of the nodes is adopted starting from the origin and going in the $x_{3}$-direction first, and then $x_{2}$ - and $x_{1}$-direction in turn, so that the resulting matrix $A$ can be partitioned into block matrices corresponding to the subdomains, respectively. Using tensor product notation $\otimes$ (See [4], and [9] in which tensor products in connection with BVP's were introduced.), the matrix $B$ in (23) can be written as

$$
\begin{equation*}
B=T_{n}(\beta) \otimes I_{n} \otimes I_{n}+I_{n} \otimes T_{n}(2) \otimes I_{n}+I_{n} \otimes I_{n} \otimes T_{n}(2) \tag{24}
\end{equation*}
$$

where $T_{j}(x)$ is defined in (6) and $\beta=2+q h^{2}$.
Define $l+1=\frac{\ell}{h}$ and $m+1=\frac{\eta}{h}$ such that $n=\kappa m-l(\kappa-1)$ and $l<\frac{m-1}{2}$. The numerical version of SAM for the problem (22) is equivalent to a block GaussSeidel iteration procedure for a new linear system, called the Schwarz Enhanced Matrix Equation ,

$$
\begin{equation*}
\tilde{B} \tilde{x}=\tilde{f} \tag{25}
\end{equation*}
$$

with

$$
\begin{equation*}
\tilde{B}=\tilde{A}(\beta) \otimes I_{n} \otimes I_{n}+I_{\kappa m} \otimes T_{n}(2) \otimes I_{n}+I_{\kappa m} \otimes I_{n} \otimes T_{n}(2) \tag{26}
\end{equation*}
$$

where $I_{\kappa m}$ is the $\kappa m \times \kappa m$ identity matrix and $\tilde{A}(\beta)$ is the $\kappa \times \kappa$ block matrix as that defined in (11), which is the case of $\kappa=3$. Note that each diagonal block in $\tilde{A}(\beta)$ is $m \times m$ matrix.

Let $X_{n}$ be the $n \times n$ orthogonal matrix whose columns are the eigenvectors of the matrix $T_{n}(2)$. Since the eigenvalues of the matrix $T_{n}(2)$ are known to be $\gamma_{i}=2+2 \cos \left(\frac{i \pi}{n+1}\right), i=1,2, \cdots, n$, we can write

$$
\begin{equation*}
X_{n}^{T} T_{n}(2) X_{n}=D_{n} \equiv \operatorname{diag}\left(\gamma_{1}, \gamma_{2}, \cdots, \gamma_{n}\right) \tag{27}
\end{equation*}
$$

Let $X=I_{\kappa m} \otimes I_{n} \otimes X_{n}$, then its inverse is given by $X^{-1}=I_{\kappa m} \otimes I_{n} \otimes X_{n}^{T}$, so we have

$$
\begin{aligned}
X^{-1} \tilde{B} X= & \left(I_{\kappa m} \otimes I_{n} \otimes X_{n}^{T}\right)\left(\tilde{A}(\beta) \otimes I_{n} \otimes I_{n}\right)\left(I_{\kappa m} \otimes I_{n} \otimes X_{n}\right) \\
& +\left(I_{\kappa m} \otimes I_{n} \otimes X_{n}^{T}\right)\left(I_{\kappa m} \otimes T_{n}(2) \otimes I_{n}\right)\left(I_{\kappa m} \otimes I_{n} \otimes X_{n}\right) \\
& +\left(I_{\kappa m} \otimes I_{n} \otimes X_{n}^{T}\right)\left(I_{\kappa m} \otimes I_{n} \otimes T_{n}(2)\right)\left(I_{\kappa m} \otimes I_{n} \otimes X_{n}\right) \\
= & \left(I_{\kappa m} \tilde{A}(\beta) I_{\kappa m}\right) \otimes I_{n} \otimes\left(X_{n}^{T} I_{n} X_{n}\right) \\
& +I_{\kappa m} \otimes T_{n}(2) \otimes\left(X_{n}^{T} I_{n} X_{n}\right) \\
& +I_{\kappa m} \otimes I_{n} \otimes\left(X_{n}^{T} T_{n}(2) X_{n}\right) \\
= & \tilde{A}(\beta) \otimes I_{n} \otimes I_{n}+I_{\kappa m} \otimes T_{n}(2) \otimes I_{n}+I_{\kappa m} \otimes I_{n} \otimes D_{n} .
\end{aligned}
$$

If $P$ is the permutation matrix that maps

$$
\begin{array}{lll} 
& \text { row } & (i-1) n^{2}+(j-1) n+k \\
\text { into } & \text { row } & (k-1) n \kappa m+(i-1) n+j
\end{array}
$$

for $i=1,2, \cdots, \kappa m, j=1,2, \cdots, n, k=1,2, \cdots, n$, then we have

$$
\begin{align*}
\breve{B}= & P^{-1} X^{-1} \tilde{B} X P \\
= & P^{-1}\left(\tilde{A}(\beta) \otimes I_{n} \otimes I_{n}\right) P+P^{-1}\left(I_{\kappa m} \otimes T_{n}(2) \otimes I_{n}\right) P  \tag{28}\\
& +P^{-1}\left(I_{\kappa m} \otimes I_{n} \otimes D_{n}\right) P \\
= & I_{n} \otimes \tilde{A}(\beta) \otimes I_{n}+I_{n} \otimes I_{\kappa m} \otimes T_{n}(2)+D_{n} \otimes I_{\kappa m} \otimes I_{n}
\end{align*}
$$

Note that the solution $\tilde{x}$ of linear system (25) is obtained by $\tilde{x}=X P \breve{x}$ if we solve the linear system

$$
\begin{equation*}
\breve{B} \breve{x}=\breve{f} \tag{29}
\end{equation*}
$$

where $\breve{f}=P^{-1} X^{-1} \tilde{f}$ with $\tilde{f}$ in (25).
Likewise, using $Y=I_{n} \otimes I_{\kappa m} \otimes X_{n}$, we have

$$
\begin{aligned}
Y^{-1} \breve{B} Y= & \left(I_{n} \otimes I_{\kappa m} \otimes X_{n}^{T}\right)\left(I_{n} \otimes \tilde{A}(\beta) \otimes I_{n}\right)\left(I_{n} \otimes I_{\kappa m} \otimes X_{n}\right) \\
& +\left(I_{n} \otimes I_{\kappa m} \otimes X_{n}^{T}\right)\left(I_{n} \otimes I_{\kappa m} \otimes T_{n}(2)\right)\left(I_{n} \otimes I_{\kappa m} \otimes X_{n}\right) \\
& +\left(I_{n} \otimes I_{\kappa m} \otimes X_{n}^{T}\right)\left(D_{n} \otimes I_{\kappa m} \otimes I_{n}\right)\left(I_{n} \otimes I_{\kappa m} \otimes X_{n}\right) \\
= & I_{n} \otimes \tilde{A}(\beta) \otimes\left(X_{n}^{T} I_{n} X_{n}\right)+I_{n} \otimes I_{\kappa m} \otimes\left(X_{n}^{T} T_{n}(2) X_{n}\right) \\
& +D_{n} \otimes I_{\kappa m} \otimes\left(X_{n}^{T} I_{n} X_{n}\right) \\
= & I_{n} \otimes \tilde{A}(\beta) \otimes I_{n}+I_{n} \otimes I_{\kappa m} \otimes D_{n}+D_{n} \otimes I_{\kappa m} \otimes I_{n} .
\end{aligned}
$$

If $Q$ is the permutation matrix that maps

$$
\begin{array}{ll}
\text { row } & (k-1) n \kappa m+(i-1) n+j \\
\text { row } & (k-1) n \kappa m+(j-1) \kappa m+i
\end{array}
$$

into
for $i=1,2, \cdots, \kappa m, j=1,2, \cdots, n, k=1,2, \cdots, n$, then we have

$$
\begin{align*}
\hat{B}= & Q^{-1} X^{-1} \breve{B} X Q \\
= & Q^{-1}\left(I_{n} \otimes \tilde{A}(\beta) \otimes I_{n}\right) Q+Q^{-1}\left(I_{n} \otimes I_{\kappa m} \otimes D_{n}\right) Q \\
& +Q^{-1}\left(D_{n} \otimes I_{\kappa m} \otimes I_{n}\right) Q  \tag{30}\\
= & I_{n} \otimes I_{n} \otimes \tilde{A}(\beta)+I_{n} \otimes D_{n} \otimes I_{\kappa m}+D_{n} \otimes I_{n} \otimes I_{\kappa m} \\
= & \Phi\left[\tilde{A}\left(\zeta_{j, k}\right)\right]_{\substack{j=1,2, \cdots, n \\
k=1,2, \cdots, n}}
\end{align*}
$$

where $\zeta_{j, k}=\beta+\gamma_{j}+\gamma_{k}$ for $j=1,2, \cdots, n$ and $k=1,2, \cdots, n$ and

$$
\begin{align*}
&\left.\Phi\left[s_{(j, k)}\right]\right]_{j=1,2, \cdots, n}^{j=1,2, \cdots, n} \\
&=\operatorname{diag}( \operatorname{diag}\left(s_{(1,1)}, s_{(2,1)}, \cdots, s_{(n, 1)}\right), \\
& \operatorname{diag}\left(s_{(1,2)}, s_{(2,2)}, \cdots, s_{(n, 2)}\right),  \tag{31}\\
& \cdots \cdots \\
& \operatorname{diag}\left(s_{(1, n)}, s_{(2, n)}, \cdots, s_{(n, n)}\right)
\end{align*}
$$

which represents a diagonal matrix of diagonal matrices of entries $s_{(j, k)}$ 's.
Note that the solution $\breve{x}$ of linear system (29) is obtained by $\breve{x}=Y Q \hat{x}$ if we solve the linear system

$$
\begin{equation*}
\hat{B} \hat{x}=\hat{f} \tag{32}
\end{equation*}
$$

where

$$
\hat{f}=Q^{-1} Y^{-1} \breve{f}
$$

with $\breve{f}$ in (29), so that

$$
\begin{aligned}
\hat{f} & =Q^{-1} Y^{-1} \breve{f} \\
& =Q^{-1} Y^{-1}\left(P^{-1} X^{-1} \tilde{f}\right)
\end{aligned}
$$

with $\tilde{f}$ in (25). Finally $\tilde{x}$ in (25) is computed by

$$
\tilde{x}=X P \breve{x}=X P(Y Q \hat{x})
$$

with $\hat{x}$ in (32).
From (30) and (32), we know that the three-dimensional problem (25) is reduced to $n^{2}$ number of one dimensional problems

$$
\tilde{A}\left(\zeta_{j, k}\right)=\hat{f}_{j, k}, j=1,2, \cdots, n, k=1,2, \cdots, n,
$$

where $\hat{f}_{j, k}$ is the corresponding sub-vector of $\hat{f}$.
The Multi-Parameterized Schwarz Enhanced Matrix for $\hat{B}$ in (30) is defined as

$$
\begin{equation*}
B^{\prime}=\Phi\left[A^{\prime}\left(\zeta_{j, k}, \mathbf{a}\right)\right]_{\substack{j=1,2, \ldots, n \\ k=1,2, \ldots, n}} \tag{33}
\end{equation*}
$$

where $A^{\prime}(x, \mathbf{a})$ is defined in (17). If we let

$$
\begin{align*}
M & =\Phi\left[M\left(\zeta_{j, k}, \mathbf{a}\right)\right] \begin{array}{l}
j=1,2, \cdots, n \\
k=1,2, \cdots, n \\
j
\end{array}, \begin{array}{l}
j, 1,2, \cdots, n \\
k
\end{array}, 1,2, \ldots, n
\end{align*}
$$

where $M(x, \mathbf{a})$ and $N(x, \mathbf{a})$ are defined in (19), then we can write the multiparameterized enhanced matrix $B^{\prime}$ in (33) as

$$
\begin{equation*}
B^{\prime}=M-N \tag{35}
\end{equation*}
$$

which is called a Multi-Parameterized Schwarz Splitting (MPSS). The convergence behavior of MPSS depends on the spectral radius of the following block Jacobi matrix

$$
\begin{equation*}
J=M^{-1} N=\Phi\left[L_{j, k}(\mathbf{a})\right]_{\substack{j=1,2, \cdots, n \\ k=1,2, \cdots, n}} \tag{36}
\end{equation*}
$$

where

$$
L_{j, k}(\mathbf{a})=M\left(\zeta_{j, k}, \mathbf{a}\right)^{-1} N\left(\zeta_{j, k}, \mathbf{a}\right)
$$

for $j=1,2, \cdots, n$ and for $k=1,2, \cdots, n$.
In [7], one failed to determine a parameter vector a such that the spectral radius of the block Jacobi matrix $J$ in (36) is zero because it is not possible to find such a parameter vector a that makes all of the spectral radii of the diagonal blocks $L_{j, k}(\mathbf{a})$ 's in (36) zero simultaneously.

So instead of fixed parameter $\mathbf{a}$, we adopt multi-parameter vector $\mathbf{a}_{j, k}$ for each diagonal block as follows

$$
\begin{equation*}
J=M^{-1} N=\Phi\left[L_{j, k}\left(\mathbf{a}_{j, k}\right)\right]_{\substack{j=1,2, \cdots, n \\ k=1,2, \cdots, n}} \tag{37}
\end{equation*}
$$

where

$$
\mathbf{a}_{j, k}=\left(\alpha_{0, j, k}, \alpha_{1, j, k}, \alpha_{2, j, k}, \cdots, \alpha_{\kappa, j, k}\right)
$$

for $j=1,2, \cdots, n$ and $k=1,2, \cdots, n$. Note these triple indices $(i, j, k)$ in multi-parameter $\alpha_{i, j, k}$ are related to the idea that one adopts variable parameter $\omega_{i}(y, z)$ instead of constant parameter $\omega_{i}$ in (2) along the $i$-th interface, i.e., we have

$$
\begin{equation*}
B_{i}(u)=\omega_{i}(y, z) u+\left(1-\omega_{i}(y, z)\right) \frac{\partial u}{\partial n} \tag{38}
\end{equation*}
$$

as the mixed interface condition on the $i$-th interface boundary.
Now, using these triple-index multi-parameter $\alpha_{i, j, k}$ 's, we have the following theorem for three-dimensional multi-parameterized Schwarz splitting $B^{\prime}=M-$ $N$ in (35).

Theorem 3.1. For $j=1,2, \cdots, n$ and $k=1,2, \cdots, n$, let $\theta_{j, k}=\cosh ^{-1}\left(\frac{\zeta_{j, k}}{2}\right)$ with $\zeta_{j, k}$ in (30) and let $p \in\{1,2, \cdots, \kappa-1\}$ and let

$$
\Theta_{j, k}(x) \equiv \begin{cases}\sinh \left(x \theta_{j, k}\right), & \theta>0 \\ x & , \theta=0\end{cases}
$$

If the values $\alpha_{i, j, k}$ for each $j=1,2, \cdots, n$ and each $k=1,2, \cdots, n$ and each $i=0,1, \cdots, \kappa$ are given by

$$
\begin{aligned}
& \alpha_{0, j, k}=\alpha_{\kappa, j, k}=0 \\
& \alpha_{i, j, k}=\frac{\Theta_{j, k}(m-l)-\alpha_{i-1, j, k} \Theta_{j, k}(m-l-1)}{\Theta_{j, k}(m-l+1)-\alpha_{i-1, j, k} \Theta_{j, k}(m-l)}, \quad i=1,2, \cdots, p, \\
& \alpha_{i, j, k}=\frac{\Theta_{j, k}(m-l)-\alpha_{i+1, j, k} \Theta_{j, k}(m-l-1)}{\Theta_{j, k}(m-l+1)-\alpha_{i+1, j, k} \Theta_{j, k}(m-l)}, \quad i=p+1, \cdots, \kappa-1,
\end{aligned}
$$

then the spectral radius of the block Jacobi matrix $J$ in (37) is zero.

## 4. Numerical Experiments

In this section, we present a numerical experiment to prove the result of the previous section. we will compare the results of Multi-Parameterized SAM (MP$S A M)$ with those of the Classical SAM. Consider the following model problem

$$
\begin{gather*}
-\nabla^{2} u(x, y, z)=0, \quad(x, y, z) \in \Omega=(0,1) \times(0,1) \times(0,1),  \tag{39}\\
u(x, y, z) \stackrel{(x, y, z), \quad(x, y, z) \in \Gamma,}{=f(x)} .
\end{gather*}
$$

where $\Gamma$ is the boundary of $\Omega$, with solution

$$
u(x, y, z)=\sin (2 \pi x) \cos (2 \pi y) \sin (2 \pi z) .
$$

In all the experiments, the vector with all its components 0.0 was used as initial guess of the solution vector. The relative residual $r_{\kappa}$ is computed as the

Table 1. The classical $S A M$ is applied to the BVP (39).

| $m$ | relative residual $r_{\kappa}(\max ($ err $))$ |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
|  |  | $\kappa=2$ | $\kappa=4$ | $\kappa=8$ |
|  |  | $8.4817 \mathrm{E}-02$ | $6.3237 \mathrm{E}-02$ | $5.8736 \mathrm{E}-02$ |
|  |  | $(7.7862 \mathrm{E}-02)$ | $(1.1697 \mathrm{E}-01)$ | $(1.9661 \mathrm{E}-01)$ |
| 8 | 4 | $1.6126 \mathrm{E}-02$ | $7.6499 \mathrm{E}-04$ | $2.4438 \mathrm{E}-03$ |
|  |  | $(3.3959 \mathrm{E}-02)$ | $(8.6187 \mathrm{E}-03)$ | $(1.9430 \mathrm{E}-03)$ |

Table 2. The MPSAM is applied to the BVP (39).

|  |  | relative residual $r_{\kappa}(\max ($ err $))$ |  |  |
| :---: | :---: | :---: | :---: | :---: |
| $m$ |  | $\kappa=2$ | $\kappa=4$ | $\kappa=8$ |
| 8 |  | $2.7744 \mathrm{E}-16$ | $4.1060 \mathrm{E}-16$ | $6.0494 \mathrm{E}-16$ |
|  |  | $(1.3282 \mathrm{E}-02)$ | $(3.7107 \mathrm{E}-03)$ | $(9.9877 \mathrm{E}-04)$ |
| 8 | 4 | $3.4301 \mathrm{E}-16$ | $3.2078 \mathrm{E}-16$ | $5.0200 \mathrm{E}-16$ |
|  |  | $(1.9391 \mathrm{E}-02)$ | $(7.5565 \mathrm{E}-03)$ | $(2.4514 \mathrm{E}-03)$ |

ratio of $\ell_{2}$-norms of the residuals of the corresponding system of equations after $\kappa$ iterations, i.e.,

$$
r_{\kappa}=\frac{\left\|B^{\prime} x^{(\kappa)}-\hat{f}\right\|_{2}}{\left\|B^{\prime} x^{(0)}-\hat{f}\right\|_{2}}
$$

Table 1 shows the relative residuals of SAM computed after $\kappa$ iterations for each number of subdomains $(\kappa=2,4,8)$, and number of local grids $(m=8)$ and minimum and half overlaps $(l=1,4)$. Table 2 shows the performance of MPSAM under the same conditions. It shows the optimal convergence. Indeed, the relative residuals by MPSAM are less than $5.02 \times 10^{-15}$ after $\kappa$ iterations for the case of $\kappa$ subdomains.

The convergence rate is very sensitive to the computed optimal value of parameter $\alpha_{i, j, k}$ 's and the symmetric choice of them (i.e. Take $p=[k / 2]$ in Theorem (3.1)) reduces the error propagation when we compute the optimal value of parameters $\alpha_{i, j, k}$ 's.
