Abstract

The assessment of specific impacts on the environment is a preventive measure for environmental protection which is based on the definition and proposal of measures that can prevent harmful effects, reduce or eliminate them. In the physical sense, vibration is the oscillating motion of an object with the effect of internal or external forces applied to it. People who touch a vibrating surface or object will feel these vibrations. In general, there are two types of vibration exposure. The first are the vibrations of the hands and arms transmitted by the held parts of tools or machinery. The second are whole-body vibrations transmitted from a seat or surface to a motorized car. The risk of injury to workers exposed to vibration varies depending on the size, frequency, type, duration of exposure, and organ affected. The purpose of this paper is to review the measurements of vibrations in the Kosovo Energy Corporation in the mine Sibovc Southwest, where coal with a rotary excavator is exploited and the evaluation of vibrations for working conditions for workers working in that environment and improving working conditions for the measurement of vibrations we have used the device Minimate DS 078, the purpose of such environmental impact assessment is to collect data and predict the harmful impacts on the environment, namely the impact on water, air, soil, life and health of as well as identify and propose measures that could prevent, reduce or eliminate altogether.

Keywords:

Environment, Vibrations, Software, Excavator

1. Introduction

Vibration measurements were performed at the Kosovo Energy Corporation, respectively at the Sibovci South mine. The measurements were made in 2021. Vibration measurements were made at four measuring points. During the measurements at work were five rotary excavators for coal excavation for the production of electricity with initials: Er - 1B, Er - 3B, Er. - 4B, Er. -4B, and Er. -6B.

Working methodology: Vibration measurements were performed according to EU Standard no. 44/2002.Vibration measurement was performed with the instrument Vibration meter "INSTATEL" Minimate DS

3. Conclusion

Table 7 shows the most important data obtained from the software device for the four measurements in the mine, with the measurement technique it can be seen that none of the four measurements have exceeded the measurement parameters distributed throughout the mine. The measured results and comparison with other measurement measurements of earlier years are very close to those of measurements for 2021.

The graphs show a comparison between the mean values of the measurement time and the comparative results of the measurements from the vibration source are within the allowable limits.

Based on the measured values, presented in tables 1, 2, 3 and 4 given in this paper we can conclude that the measured values in tables no. 1, no. 2, no. 3, and no. 4 are allowed, based on standard no. 44/2002 / EU. The time when we performed the measurements according to the report of the dispatcher at work were the following excavators: Er - 1B, Er - 3B, Er. - 4B, Er.-4B, and Er.-6B. The diagrams are also attached to the measurement report by the software device.
