

## ON $\phi$ -( $n, d$ ) RINGS AND $\phi$ - $n$ -COHERENT RINGS

YOUNES EL HADDAOUI, HWANKOO KIM, AND NAJIB MAHDOU

**ABSTRACT.** This paper introduces and studies a generalization of  $(n, d)$ -rings introduced and studied by Costa in 1994 to rings with prime nilradical. Among other things, we establish that the  $\phi$ -von Neumann regular rings are exactly either  $\phi$ -( $0, 0$ ) or  $\phi$ -( $1, 0$ ) rings and that the  $\phi$ -Prüfer rings which are strongly  $\phi$ -rings are the  $\phi$ -( $1, 1$ ) rings. We then introduce a new class of rings generalizing the class of  $n$ -coherent rings to characterize the nonnil-coherent rings introduced and studied by Bacem and Benhissi.

### 1. Introduction

All rings considered in this paper are assumed to be commutative with nonzero identity and prime nilradical. We use  $\text{Nil}(R)$  to denote the set of nilpotent elements of  $R$ , and  $Z(R)$  to denote the set of zero-divisors of  $R$ . A ring with  $\text{Nil}(R)$  that is divided prime (i.e.,  $\text{Nil}(R) \subset xR$  for every  $x \in R \setminus \text{Nil}(R)$ ) is called a  $\phi$ -ring. Let  $\mathcal{H}$  be the set of all  $\phi$ -rings. A ring  $R$  is called a strongly  $\phi$ -ring if  $R \in \mathcal{H}$  and  $Z(R) = \text{Nil}(R)$ . Let  $R$  be a ring and  $M$  be an  $R$ -module, we define

$$\phi\text{-tor}(M) = \{x \in M \mid sx = 0 \text{ for some } s \in R \setminus \text{Nil}(R)\}.$$

If  $\phi\text{-tor}(M) = M$ , then  $M$  is called a  $\phi$ -torsion module, and if  $\phi\text{-tor}(M) = 0$ , then  $M$  is called a  $\phi$ -torsion free module. An ideal  $I$  of  $R$  is said to be nonnil if  $I \not\subseteq \text{Nil}(R)$ . An  $R$ -module  $M$  is said to be  $\phi$ -divisible if  $M = sM$  for every  $s \in R \setminus \text{Nil}(R)$ . An  $R$ -module  $M$  is said to be  $\phi$ -uniformly torsion ( $\phi$ -u-torsion for short) if  $sM = 0$  for some  $s \in R \setminus \text{Nil}(R)$  [12, Definition 2.2].

Let  $R$  be a ring and  $n$  be a nonnegative integer. According to Costa [9], an  $R$ -module  $M$  is said to be  $n$ -presented if there exists an exact sequence  $F_n \rightarrow F_{n-1} \rightarrow \cdots \rightarrow F_0 \rightarrow M \rightarrow 0$  such that each  $F_i$  is a finitely generated free  $R$ -module, equivalently each  $F_i$  is a finitely generated projective  $R$ -module.

*Key words and phrases.* Nonnil-coherent ring,  $\phi$ -Noetherian ring,  $\phi$ - $n$ -presented module, nonnil-FP-injective module,  $\phi$ -( $n, d$ )-injective modules,  $\phi$ -( $n, d$ )-flat modules,  $\phi$ -( $n, d$ )-ring,  $\phi$ -weak-( $n, d$ )-ring,  $\phi$ - $n$ -coherent ring,  $\phi$ - $n$ -von Neumann regular ring.

If  $M$  is a  $\phi$ -torsion  $R$ -module that is  $n$ -presented, then  $M$  is called a  $\phi$ - $n$ -presented module. A finite  $n$ -presentation of a  $\phi$ -torsion  $R$ -module is said to be a  $\phi$ - $n$ -presentation. Obviously, every finitely generated projective module is  $n$ -presented for every  $n$ . A module is 0-presented (resp., 1-presented) if and only if it is finitely generated (resp., finitely presented), and every  $m$ -presented module is  $n$ -presented for any  $n \leq m$ . A ring  $R$  is called  $n$ -coherent if every  $n$ -presented  $R$ -module is  $(n+1)$ -presented. It is easy to see that  $R$  is 0-coherent (resp., 1-coherent) if and only if it is Noetherian (resp., coherent), and every  $n$ -coherent ring is  $m$ -coherent for any  $m \geq n$ . The  $n$ -coherent ring is further studied in detail in [10, 11]. Costa introduced a doubly filtered set of classes of rings to categorize the structure of non-Noetherian rings for nonnegative integers  $n$  and  $d$ . We say that a ring  $R$  is an  $(n, d)$ -ring if  $\text{pd}_R(M) \leq d$  for every  $n$ -presented  $R$ -module  $M$  (as usual,  $\text{pd}_R(M)$  denotes the projective dimension of  $M$  as an  $R$ -module). An integral domain with this property is called an  $(n, d)$ -domain. For example, the  $(n, 0)$ -domains are the fields, the  $(0, 1)$ -domains are the Dedekind domains, and the  $(1, 1)$ -domains are the Prüfer domains [9]. The  $(n, d)$ -ring is further studied in detail in [16, 19, 21–23]. We call a commutative ring an  $n$ -von Neumann regular ring if it is an  $(n, 0)$ -ring. Thus, the 1-von Neumann regular rings are exactly the von Neumann regular rings [9, Theorem 1.3].

In 2004, D. Zhou [30] introduced and studied a new class of modules with two parameters  $n, d \in \mathbb{N}$ , the set of nonnegative integers: an  $R$ -module  $N$  is said to be  $(n, d)$ -injective (resp.,  $(n, d)$ -flat) if  $\text{Ext}_R^{d+1}(M, N) = 0$  (resp.,  $\text{Tor}_{d+1}^R(M, N) = 0$  for  $n \geq 1$ ) for each  $n$ -presented  $R$ -module  $M$ . In particular, the  $(0, 0)$ -injective modules are injective, the  $(1, 0)$ -injective modules are FP-injective (i.e., modules  $N$  in which we have  $\text{Ext}_R^1(M, N) = 0$  for every finitely presented  $R$ -module  $M$ ), more generally, an  $R$ -module  $M$  is  $(0, d)$ -injective if the injective dimension of  $M$  is at most  $d$ . An  $R$ -module  $M$  is  $(1, 0)$ -flat if it is flat, and  $M$  is  $(1, d)$ -flat if the flat dimension of  $M$  is at most  $d$ . A ring  $R$  is called a weak- $(n, d)$ -ring with  $n \geq 1$  if each  $n$ -presented module has a flat dimension at most  $d$ . In particular, the weak- $(1, 0)$ -rings are von Neumann regular rings. D. Zhou established that a ring  $R$  is  $n$ -coherent if and only if every  $(n+1, 0)$ -injective module is  $(n, 0)$ -injective, and if  $n \geq 1$ , then  $R$  is  $n$ -coherent if and only if every  $(n+1, 0)$ -flat module is  $(n, 0)$ -flat [30, Theorem 3.4].

In 1996, J. Chen and N. Ding [8] introduced a generalization of flat modules and injective modules by a nonzero positive integer parameter. An  $R$ -module  $N$  is said to be  $n$ -flat (with  $n \geq 1$ ) (resp.,  $n$ -FP-injective) if  $\text{Tor}_n^R(M, N) = 0$  (resp.,  $\text{Ext}_R^n(M, N) = 0$ ) for every  $n$ -presented  $R$ -module  $M$ . In other words, the  $n$ -flat (resp.,  $n$ -FP-injective) modules are  $(n, n-1)$ -flat (resp.,  $(n, n-1)$ -injective). They characterized the  $n$ -coherent rings by the  $n$ -flat modules and the  $n$ -FP-injective modules (see [8, Theorem 3.1]).

In [2], D. F. Anderson and A. Badawi introduced a class of  $\phi$ -rings called  $\phi$ -Prüfer. A  $\phi$ -ring  $R$  is said to be  $\phi$ -Prüfer if  $R/\text{Nil}(R)$  is a Prüfer domain [2, Theorem 2.6]. All  $\phi$ -Prüfer rings are Prüfer [2, Theorem 2.14], if additionally  $Z(R) = \text{Nil}(R)$ , then every Prüfer ring is  $\phi$ -Prüfer [2, Theorem 2.16]. In [29], G. Tang, F. Wang, and W. Zhao introduced a class of  $\phi$ -rings which are called  $\phi$ -von Neumann regular rings. An  $R$ -module  $M$  is said to be  $\phi$ -flat if for every monomorphism  $f : A \rightarrow B$  with  $\text{Coker}(f)$   $\phi$ -torsion,  $f \otimes 1 : A \otimes_R M \rightarrow B \otimes_R M$  is an  $R$ -monomorphism [29, Definition 3.1]. An  $R$ -module  $M$  is  $\phi$ -flat if and only if  $M_{\mathfrak{p}}$  is  $\phi$ -flat for every prime ideal  $\mathfrak{p}$  of  $R$ , if and only if  $M_{\mathfrak{m}}$  is  $\phi$ -flat for every maximal ideal  $\mathfrak{m}$  of  $R$  [29, Theorem 3.5]. A  $\phi$ -ring  $R$  is said to be a  $\phi$ -von Neumann regular ring if all  $R$ -modules are  $\phi$ -flat, which is equivalent to saying that  $R/\text{Nil}(R)$  is a von Neumann regular ring [29, Theorem 4.1].

Recall from [4] that a  $\phi$ -ring  $R$  is said to be nonnil-Noetherian if  $R/\text{Nil}(R)$  is a Noetherian domain, which is equivalent to saying that every nonnil ideal of  $R$  is finitely generated. Note that this notion coincides with the notion of  $\phi$ -Noetherian rings in the work of the authors of [5].

In [3], K. Bacem and B. Ali introduced two new classes of  $\phi$ -rings: a  $\phi$ -ring  $R$  is said to be  $\phi$ -coherent if  $R/\text{Nil}(R)$  is a coherent domain [3, Corollary 3.1]; a  $\phi$ -ring  $R$  is said to be nonnil-coherent if every finitely generated nonnil ideal of  $R$  is finitely presented, which is equivalent to saying that  $R$  is  $\phi$ -coherent and  $(0 : r)$  is a finitely generated ideal of  $R$  for every  $r \in R \setminus \text{Nil}(R)$  [24, Proposition 1.3]. Following Y. El Haddaoui, H. Kim, and N. Mahdou [13], a submodule  $N$  of an  $R$ -module  $M$  is said to be a  $\phi$ -submodule if  $M/N$  is a  $\phi$ -torsion module [13, Definition 2.1]. For  $R \in \mathcal{H}$ , an  $R$ -module  $M$  is said to be nonnil-coherent if  $M$  is finitely generated and every finitely generated  $\phi$ -submodule of  $M$  is finitely presented [13, Definition 2.2]. It is easy to see that every coherent module over a  $\phi$ -ring is nonnil-coherent. Next they established in [13, Theorem 2.6] the analog of the well-known behavior of the relation between the coherent rings and the finitely generated submodules of a finitely generated free module.

Y. El Haddaoui and N. Mahdou [12] introduced and studied the  $\phi$ -(weak) global dimension of rings with prime nilradical. An  $R$ -module  $P$  is said to be  $\phi$ -u-projective if  $\text{Ext}_R^1(P, N) = 0$  for any  $\phi$ -u-torsion  $R$ -module  $N$  [12, Definition 3.1]. The  $\phi$ -projective dimension of  $M$  over  $R$ , denoted by  $\phi\text{-pd}_R M$ , is said to be at most  $n$  (where  $n \in \mathbb{N}^*$ ) if either  $M = 0$  or  $M$  is not a  $\phi$ -u-projective module which satisfies  $\text{Ext}_R^{n+1}(M, N) = 0$  for every  $\phi$ -u-torsion module  $N$ . In addition, if  $n$  is the least such nonnegative integer, then we set  $\phi\text{-pd}_R M = n$ . If no such  $n$  exists, we set  $\phi\text{-pd}_R M = \infty$  [12, Definition 3.2]. For a ring  $R$  with  $Z(R) = \text{Nil}(R)$ , define

$$\phi\text{-gl. dim}(R) = \sup \{ \phi\text{-pd}_R R/I \mid I \text{ is a nonnil ideal of } R \},$$

which is called the  $\phi$ -global dimension of  $R$  [12, Definition 4.1]. Similarly, the  $\phi$ -flat dimension of an  $R$ -module  $M$ , denoted by  $\phi\text{-fd}_R M$ , is said to be at most  $n$  (where  $n \in \mathbb{N}^*$ ) if either  $M = 0$  or  $M$  is not  $\phi$ -flat which satisfies  $\text{Tor}_{n+1}^R(M, N) = 0$  for every  $\phi$ -u-torsion module  $N$ . In addition, if  $n$  is at least

one such nonnegative integer, then we set  $\phi\text{-fd}_R M = n$ . If there is no such  $n$ , we set  $\phi\text{-fd}_R M = \infty$  [12, Definition 5.7]. Let  $R$  be a ring. Define for a ring  $R$  with  $Z(R) = \text{Nil}(R)$

$$\begin{aligned} \phi\text{-w. gl. dim}(R) &= \sup \{ \phi\text{-fd}_R M \mid M \text{ is } \phi\text{-torsion} \} \\ &= \sup \{ \phi\text{-fd}_R M \mid M \text{ is } \phi\text{-u-torsion} \} \\ &= \sup \{ \phi\text{-fd}_R M \mid M \text{ is finitely presented } \phi\text{-torsion} \} \\ &= \sup \{ \phi\text{-fd}_R M \mid M \text{ is finitely presented } \phi\text{-u-torsion} \} \\ &= \sup \{ \phi\text{-fd}_R R/I \mid I \text{ is a nonnil ideal of } R \} \\ &= \sup \{ \phi\text{-fd}_R R/I \mid I \text{ is a finitely generated nonnil ideal of } R \}, \end{aligned}$$

which is called the  $\phi$ -weak global dimension of  $R$  [12, Definition 5.10]. If  $R \in \mathcal{H}$ , then  $R$  is a  $\phi$ -von Neumann regular ring if and only if  $\phi\text{-w. gl. dim}(R) = 0$  [12, Theorem 5.29], which is equivalent to saying that  $\phi\text{-gl. dim}(R) = 0$  [12, Corollary 5.33]. A strongly  $\phi$ -ring is  $\phi$ -Prüfer if and only if  $\phi\text{-w. gl. dim}(R) \leq 1$  [12, Corollary 5.27] if and only if every finitely generated nonnil ideal of  $R$  is  $\phi$ -u-projective [12, Theorem 5.41].

Our paper consists of three sections, including the introduction. In Section 2 we introduce  $\phi$ - $(n, d)$ -rings, which are generalizations of the  $(n, d)$ -rings (where  $n, d \geq 0$  are integers) introduced and studied by D. L. Costa [9]. An  $R$ -module  $N$  is said to be  $\phi$ - $(n, d)$ -injective or nonnil  $(n, d)$ -injective if  $\text{Ext}_R^{d+1}(R/I, N) = 0$  for every nonnil ideal  $I$  of  $R$  such that  $R/I$  is a  $\phi$ - $n$ -presented module (see Definition 2). An  $R$ -module  $M$  is said to be  $\phi$ - $(n, d)$ -flat (with  $n \in \mathbb{N}^*$ , the set of positive integers) if  $\text{Tor}_{d+1}^R(R/I, M) = 0$  for every  $\phi$ - $n$ -presented module  $R/I$ , where  $I$  is a nonnil ideal of  $R$ . A ring  $R$  is said to be a  $\phi$ - $(n, d)$ -ring if every  $\phi$ - $n$ -presented module  $M$  has a  $\phi$ -projective dimension at most  $d$ . We establish in Theorem 2.22 that the  $\phi$ -von Neumann regular rings are exactly either  $\phi$ - $(0, 0)$  or  $\phi$ - $(1, 0)$  rings and that the  $\phi$ -Prüfer rings which are strongly  $\phi$ -rings are the  $\phi$ - $(1, 1)$  rings. In Section 3, we define a generalization of  $n$ -coherent rings. A ring  $R$  is said to be  $\phi$ - $n$ -coherent if all  $\phi$ - $n$ -presented  $R$ -modules are  $\phi$ - $(n+1)$ -presented. We give several equivalent conditions for a ring to be  $\phi$ - $n$ -coherent. We show that there are many similarities between coherent rings and  $\phi$ - $n$ -coherent rings. For example, a ring  $R$  is  $\phi$ - $n$ -coherent if and only if every direct product of  $R$  is a  $\phi$ - $n$ -flat  $R$ -module, if and only if every direct product of  $\phi$ - $n$ -flat  $R$ -modules is  $\phi$ - $n$ -flat, if and only if every direct limit of  $\phi$ - $n$ -FP-injective  $R$ -modules (which are  $\phi$ - $(n, n-1)$ -injectives) is  $\phi$ - $n$ -FP-injective (see Theorem 3.10).

For any undefined terminology and notation, the reader may refer to [14, 26, 27].

## 2. $\phi$ - $(n, d)$ -rings

In this section, we introduce and study a generalization of  $(n, d)$ -rings (where  $n, d \geq 0$  are integers) introduced and studied by D. L. Costa [9].

**Definition 1.** Let  $R$  be a ring. An  $R$ -module  $M$  is said to be  $n$ -presented if  $M$  has an  $n$ -finite presentation. In addition, if  $M$  is a  $\phi$ -torsion  $R$ -module, then  $M$  is said to be  $\phi$ - $n$ -presented and the  $n$ -finite presentation is called a  $\phi$ - $n$ -presentation of  $M$ .

*Remark 2.1.* If  $m \leq n$  are nonnegative integers, then every  $\phi$ - $n$ -presented module is  $\phi$ - $m$ -presented.

**Proposition 2.2.** *Let  $R$  be a ring and  $M$  be an  $R$ -module. Then*

- (1)  $M$  is  $\phi$ -0-presented if and only if  $M$  is a finitely generated  $\phi$ -torsion  $R$ -module.
- (2)  $M$  is  $\phi$ -1-presented if and only if  $M$  is a finitely presented  $\phi$ -torsion  $R$ -module.

*Proof.* This is straightforward.  $\square$

**Definition 2.** Let  $R$  be a ring and  $n, d \in \mathbb{N}$ . An  $R$ -module  $N$  is said to be  $\phi$ -( $n, d$ )-injective or nonnil ( $n, d$ )-injective if  $\text{Ext}_R^{d+1}(R/I, N) = 0$  for every nonnil ideal  $I$  such that  $R/I$  is a  $\phi$ - $n$ -presented  $R$ -module.

**Definition 3.** Let  $R$  be a ring. An  $R$ -module  $N$  is called  $\phi$ -FP-injective if  $\text{Ext}_R^1(R/I, N) = 0$  for every finitely generated nonnil ideal of  $R$ .

By [13, Theorem 2.6], a  $\phi$ -ring  $R$  is nonnil-coherent if and only if every finitely generated  $\phi$ -submodule of a finitely presented module is also finitely presented. From [24, Definition 1.7], an  $R$ -module  $N$  is said to be nonnil-FP-injective if  $\text{Ext}_R^1(M, N) = 0$  for every finitely presented  $\phi$ -torsion module  $M$ . Next, we prove that every  $\phi$ -FP-injective module over a nonnil-coherent ring is nonnil-FP-injective

**Proposition 2.3.** *If  $R$  is a nonnil-coherent ring, then every  $\phi$ -FP-injective module is nonnil-FP-injective.*

*Proof.* Let  $N$  be a  $\phi$ -FP-injective module. Then  $\text{Ext}_R^1(R/I, N) = 0$  for every finitely generated nonnil ideal  $I$  of  $R$ . We claim that  $\text{Ext}_R^1(F, N) = 0$  for every finitely presented  $\phi$ -torsion  $R$ -module  $F$ . Let  $F$  be a finitely presented  $\phi$ -torsion module. We use induction on the number of generators of  $F$ . Assume that  $F$  is a finitely presented  $\phi$ -torsion module on  $m$  generators, and let  $F'$  be the submodule generated by one of these generators. Since  $R$  is nonnil-coherent, both  $F'$  and  $F/F'$  are finitely presented  $\phi$ -torsions on less than  $m$  generators, so we get an exact sequence  $\text{Ext}_R^1(F/F', N) \rightarrow \text{Ext}_R^1(F, N) \rightarrow \text{Ext}_R^1(F', N)$ , where both end terms are zero by induction. Thus  $\text{Ext}_R^1(F, N) = 0$ . Hence  $N$  is nonnil-FP-injective.  $\square$

According to [28], an  $R$ -module  $E$  is said to be nonnil-injective if

$$\text{Ext}_R^1(R/I, E) = 0$$

for every nonnil ideal  $I$  of  $R$ . Recall from [12] that the  $\phi$ -injective dimension of  $M$  over  $R$ , denoted by  $\phi\text{-id}_R M$ , is said to be at most  $n \geq 1$  (where  $n \in \mathbb{N}$ )

if either  $M = 0$  or  $M \neq 0$  which is not nonnil-injective and which satisfies  $\text{Ext}_R^{n+1}(R/I, M) = 0$  for every nonnil ideal  $I$  of  $R$ . If  $n$  is the least nonnegative integer for which  $\text{Ext}_R^{n+1}(R/I, M) = 0$  for every nonnil ideal  $I$  of  $R$ , then we set  $\phi\text{-id}_R M = n$ . If there is no such  $n$ , we set  $\phi\text{-id}_R M = \infty$  [12, Definition 2.5], and it is easy to see that an  $R$ -module  $M$  is of  $\phi$ -injective dimension zero if and only if it is nonnil-injective. We also have that for a ring  $R$  with  $Z(R) = \text{Nil}(R)$ ,

$$\phi\text{-gl. dim}(R) = \sup \{ \phi\text{-id}_R N \mid N \text{ is a } \phi\text{-}u\text{-torsion } R\text{-module} \}.$$

**Proposition 2.4.** *Let  $N$  be an  $R$ -module. Then the following statements hold:*

- (1)  *$N$  is a  $\phi$ -(0,0)-injective module if and only if  $N$  is a nonnil-injective module.*
- (2) *If  $d \geq 1$  and  $N$  is not nonnil-injective, then  $N$  is a  $\phi$ -(0, $d$ )-injective module if and only if  $\phi\text{-id}_R N \leq d$ .*
- (3)  *$N$  is a  $\phi$ -(1,0)-injective module if and only if  $N$  is a  $\phi$ -FP-injective module.*

*Proof.* (1)  $N$  is a  $\phi$ -(0,0)-injective module if and only if  $\text{Ext}_R^1(R/I, N) = 0$  for every nonnil ideal  $I$  of  $R$ , if and only if  $N$  is a nonnil-injective module. (2) This follows from [12, Theorem 2.6]. (3) This follows from Definition 3.  $\square$

**Definition 4.** Let  $R$  be a ring and let  $(n, d) \in \mathbb{N}^* \times \mathbb{N}$ . An  $R$ -module  $M$  is said to be  $\phi$ -( $n, d$ )-flat if  $\text{Tor}_{d+1}^R(R/I, N) = 0$  for every nonnil ideal  $I$  of  $R$  such that  $R/I$  is a  $\phi$ - $n$ -presented module.

**Proposition 2.5.** *Let  $M$  be an  $R$ -module. The following statements hold:*

- (1)  *$M$  is a  $\phi$ -(1,0)-flat module if and only if  $M$  is a  $\phi$ -flat module.*
- (2) *If  $d \geq 1$  and  $M$  is not  $\phi$ -flat, then  $M$  is a  $\phi$ -(1, $d$ )-flat module if and only if  $\phi\text{-fd}_R M \leq d$ .*

*Proof.* (1)  $M$  is a  $\phi$ -(1,0)-flat module if and only if  $\text{Tor}_1^R(R/I, M) = 0$  for every finitely generated nonnil ideal  $I$  of  $R$ , if and only if  $M$  is a  $\phi$ -flat module by [29, Theorem 3.2].

(2) This follows from [12, Theorem 5.19].  $\square$

**Proposition 2.6.** *Let  $m, n$  and  $d$  be nonnegative integers such that  $m \leq n$ . Then:*

- (1) *Every  $\phi$ -( $m, d$ )-injective module is  $\phi$ -( $n, d$ )-injective.*
- (2) *If  $m \geq 1$ , then every  $\phi$ -( $m, d$ )-flat module is  $\phi$ -( $n, d$ )-flat.*

*Proof.* This follows immediately from Remark 2.1 and Definitions 2 and 4.  $\square$

Next, we give some properties related to  $\phi$ -( $n, d$ )-rings,  $\phi$ -( $n, d$ )-injective modules, and  $\phi$ -( $n, d$ )-flat modules.

**Theorem 2.7.** *Let  $\{N_i\}_{i \in \Gamma}$  be a family of  $R$ -modules. Then  $\prod_{i \in \Gamma} N_i$  is a  $\phi$ -( $n, d$ )-injective module if and only if each  $N_i$  is  $\phi$ -( $n, d$ )-injective.*

*Proof.* Let  $I$  be a nonnil ideal of  $R$  such that  $R/I$  is a  $\phi$ - $n$ -presented module. From  $\text{Ext}_R^{d+1}(R/I, \prod_{i \in \Gamma} N_i) \cong \prod_{i \in \Gamma} \text{Ext}_R^{d+1}(R/I, N_i)$ , we get that  $\prod_{i \in \Gamma} N_i$  is a  $\phi$ -( $n, d$ )-injective module if and only if each  $N_i$  is  $\phi$ -( $n, d$ )-injective.  $\square$

**Theorem 2.8.** *Let  $\{M_i\}_{i \in \Gamma}$  be a family of  $R$ -modules and  $n \geq 1$ . Then  $\bigoplus_{i \in \Gamma} M_i$  is a  $\phi$ -( $n, d$ )-flat module if and only if each  $M_i$  is  $\phi$ -( $n, d$ )-flat.*

*Proof.* Let  $I$  be a nonnil ideal of  $R$  such that  $R/I$  is a  $\phi$ - $n$ -presented module. Since

$$\text{Tor}_{d+1}^R(R/I, \bigoplus_{i \in \Gamma} M_i) \cong \bigoplus_{i \in \Gamma} \text{Tor}_{d+1}^R(R/I, M_i),$$

we get that  $\bigoplus_{i \in \Gamma} M_i$  is a  $\phi$ -( $n, d$ )-flat module if and only if each  $M_i$  is  $\phi$ -( $n, d$ )-flat.  $\square$

In this paper, for a  $\phi$ - $n$ -presented module  $M$  with a  $\phi$ - $n$ -presentation

$$F_n \rightarrow F_{n-1} \rightarrow \cdots \rightarrow F_0 \rightarrow M \rightarrow 0,$$

we set  $K_i := \ker(F_i \rightarrow F_{i-1})$  for all  $0 \leq i \leq n$  and  $F_{-1} := M$ .

The following result characterizes the  $\phi$ -( $n, d$ )-injective modules.

**Theorem 2.9.** *The following statements are equivalent for an  $R$ -module  $N$  such that  $n \geq d + 1$ .*

- (1)  $N$  is a  $\phi$ -( $n, d$ )-injective module.
- (2) For every nonnil ideal  $I$  such that  $R/I$  is a  $\phi$ - $n$ -presented module with a  $\phi$ - $n$ -presentation

$$F_n \rightarrow F_{n-1} \rightarrow \cdots \rightarrow F_0 \rightarrow R/I \rightarrow 0,$$

we get  $\text{Ext}_R^1(K_{d-1}, N) = 0$ .

- (3) For every nonnil ideal  $I$  such that  $R/I$  is a  $\phi$ - $n$ -presented module with a  $\phi$ - $n$ -presentation

$$F_n \rightarrow F_{n-1} \rightarrow \cdots \rightarrow F_0 \rightarrow R/I \rightarrow 0,$$

and every  $R$ -homomorphism  $f : K_d \rightarrow N$ ,  $f$  can be extended to  $F_d$ .

*Proof.* (1)  $\Rightarrow$  (2) Assume that  $N$  is a  $\phi$ -( $n, d$ )-injective module. Let  $I$  be a nonnil ideal of  $R$  such that  $R/I$  is a  $\phi$ - $n$ -presented module with a  $\phi$ - $n$ -presentation  $F_n \rightarrow F_{n-1} \rightarrow \cdots \rightarrow F_0 \rightarrow R/I \rightarrow 0$ . Since  $n \geq d + 1$ , it follows that  $R/I$  is  $\phi$ - $d$ -presented, and so we have  $\text{Ext}_R^{d+1}(R/I, N) \cong \text{Ext}_R^1(K_{d-1}, N) = 0$ .

(2)  $\Rightarrow$  (3) Let  $I$  be a nonnil ideal of  $R$  such that  $R/I$  is a  $\phi$ - $n$ -presented module with a  $\phi$ - $n$ -presentation  $F_n \rightarrow F_{n-1} \rightarrow \cdots \rightarrow F_0 \rightarrow R/I \rightarrow 0$ . Assume that  $\text{Ext}_R^1(K_{d-1}, N) = 0$  and let  $f : K_d \rightarrow N$  be an  $R$ -homomorphism. Then we have the following exact sequence  $0 \rightarrow K_d \rightarrow F_d \rightarrow K_{d-1} \rightarrow 0$ , which induces the exact sequence  $0 \rightarrow \text{Hom}_R(K_{d-1}, N) \rightarrow \text{Hom}_R(F_d, N) \rightarrow \text{Hom}_R(K_d, N) \rightarrow 0$ . So  $f$  can be extended to  $F_d$ .

(3)  $\Rightarrow$  (1) Let  $I$  be a nonnil ideal of  $R$  such that  $R/I$  is a  $\phi$ - $n$ -presented module with a  $\phi$ - $n$ -presentation  $F_n \rightarrow F_{n-1} \rightarrow \cdots \rightarrow F_0 \rightarrow R/I \rightarrow 0$ . By

hypothesis, we have the exact sequence  $\text{Hom}_R(F_d, N) \rightarrow \text{Hom}_R(K_d, N) \rightarrow 0$ . From the following commutative diagram with exact rows:

$$\begin{array}{ccccccc} \text{Hom}_R(F_d, N) & \longrightarrow & \text{Hom}_R(K_d, N) & \longrightarrow & \text{Ext}_R^1(K_{d-1}, N) & \longrightarrow & 0 \\ & & \parallel & & \downarrow & & \\ \text{Hom}_R(F_d, N) & \longrightarrow & \text{Hom}_R(K_d, N) & \longrightarrow & 0 & \longrightarrow & 0, \end{array}$$

we get  $\text{Ext}_R^1(K_{d-1}, N) = 0$ . In addition,  $\text{Ext}_R^{d+1}(R/I, N) \cong \text{Ext}_R^1(K_{d-1}, N) = 0$ , since  $n \geq d + 1$ . So  $N$  is a  $\phi$ - $(n, d)$ -injective module.  $\square$

The following result characterizes the  $\phi$ - $(n, d)$ -flat modules.

**Theorem 2.10.** *The following statements are equivalent for an  $R$ -module  $N$  such that  $n \geq d + 1$ .*

- (1)  $N$  is a  $\phi$ - $(n, d)$ -flat modules.
- (2) For every nonnil ideal  $I$  of  $R$  such that  $R/I$  is a  $\phi$ - $n$ -presented module with a  $\phi$ - $n$ -presentation

$$F_n \rightarrow F_{n-1} \rightarrow \cdots \rightarrow F_0 \rightarrow R/I \rightarrow 0,$$

we get  $\text{Tor}_1^R(K_{d-1}, N) = 0$ .

- (3) For every nonnil ideal  $I$  of  $R$  such that  $R/I$  is a  $\phi$ - $n$ -presented module with a  $\phi$ - $n$ -presentation

$$F_n \rightarrow F_{n-1} \rightarrow \cdots \rightarrow F_0 \rightarrow R/I \rightarrow 0,$$

the sequence  $0 \rightarrow N \otimes_R K_d \rightarrow N \otimes_R F_d$  is exact.

*Proof.* The proof is similar to the proof of Theorem 2.9.  $\square$

According to [25], an  $R$ -module  $N$  is an injective cogenerator if for every nonzero  $R$ -module  $M$ , we have  $\text{Hom}_R(M, N) \neq 0$ . In particular,  $\mathbb{Q}/\mathbb{Z}$  is an example of an injective cogenerator abelian group. For an  $R$ -module  $M$ , we set  $M^+ := \text{Hom}_{\mathbb{Z}}(M, \mathbb{Q}/\mathbb{Z})$ .

**Theorem 2.11.** *Let  $n \geq 1$  be an integer. An  $R$ -module  $N$  is  $\phi$ - $(n, d)$ -flat if and only if  $N^+$  is  $\phi$ - $(n, d)$ -injective.*

*Proof.* This follows immediately from the following isomorphism:

$$\text{Ext}_R^{d+1}(R/I, N^+) \cong \text{Tor}_{d+1}^R(R/I, N)^+. \quad \square$$

**Corollary 2.12.** *The following are equivalent for an  $R$ -module  $N$ .*

- (1)  $N$  is a  $\phi$ -flat module.
- (2)  $N^+$  is a  $\phi$ -FP-injective module.
- (3)  $N^+$  is a nonnil-injective module.

*Proof.* (1)  $\Leftrightarrow$  (2) This is straightforward by Propositions 2.4 and 2.5, and Theorem 2.11.

(1)  $\Leftrightarrow$  (3) This follows from the isomorphism:

$$\text{Tor}_1^R(R/I, N)^+ \cong \text{Ext}_R^1(R/I, N^+)$$

and [29, Theorem 3.2]. □

**Theorem 2.13.** *If  $n \geq d + 1$ , then every pure submodule of a  $\phi$ -( $n, d$ )-injective module is  $\phi$ -( $n, d$ )-injective. Also, every pure submodule of a  $\phi$ -( $n, d$ )-flat module is  $\phi$ -( $n, d$ )-flat.*

*Proof.* Assume that  $n \geq d + 1$  and let  $I$  be a nonnil ideal of  $R$  such that  $R/I$  is a  $\phi$ - $n$ -presented module with a  $\phi$ - $n$ -finite presentation

$$F_n \rightarrow F_{n-1} \rightarrow \cdots \rightarrow F_0 \rightarrow R/I \rightarrow 0.$$

Since  $n \geq d + 1$ , it follows that  $K := K_{d-1}$  is a finitely presented  $R$ -module. Let  $X$  be a pure submodule of a  $\phi$ -( $n, d$ )-injective module  $N$ . Then the sequence  $0 \rightarrow \text{Hom}_R(K, X) \rightarrow \text{Hom}_R(K, N) \rightarrow \text{Hom}_R(K, N/X) \rightarrow 0$  is exact. Furthermore, we have  $\text{Ext}_R^{d+1}(R/I, N) \cong \text{Ext}_R^1(K, N) = 0$ , and so we get the following commutative diagram with exact rows:

$$\begin{array}{ccccccc} \text{Hom}_R(K, N) & \longrightarrow & \text{Hom}_R(K, N/X) & \longrightarrow & \text{Ext}_R^1(K, X) & \longrightarrow & 0 \\ \downarrow \cong & & \downarrow \cong & & \downarrow & & \\ \text{Hom}_R(K, N) & \longrightarrow & \text{Hom}_R(K, N/X) & \longrightarrow & 0 & \longrightarrow & 0 \end{array}$$

Thus  $\text{Ext}_R^{d+1}(R/I, X) \cong \text{Ext}_R^1(K, X) = 0$ . Hence  $X$  is a  $\phi$ -( $n, d$ )-injective module.

Now, let  $X$  be a pure submodule of a  $\phi$ -( $n, d$ )-flat module  $F$ . Since  $0 \rightarrow X \rightarrow F \rightarrow F/X \rightarrow 0$  is pure exact, the induced exact sequence  $0 \rightarrow (F/X)^+ \rightarrow F^+ \rightarrow X^+ \rightarrow 0$  is split by [26, Chapter I, Exercise 40]. Since  $F^+$  is a  $\phi$ -( $n, d$ )-injective module by Theorem 2.11 and  $F^+ \cong (F/X)^+ \oplus X^+$ , it follows that  $X^+$  is a  $\phi$ -( $n, d$ )-injective module by Theorem 2.7. Therefore,  $X$  is a  $\phi$ -( $n, d$ )-flat module by Theorem 2.11. □

**Definition 5.** A ring  $R$  is said to be  $\phi$ -( $n, d$ ) if every  $\phi$ - $n$ -presented module has  $\phi$ -projective dimension at most  $d$ .

If  $n \geq 1$ , then a ring  $R$  is said to be  $\phi$ -weak-( $n, d$ ) if every  $\phi$ - $n$ -presented module has  $\phi$ -flat dimension at most  $d$ .

**Proposition 2.14.** *If  $n \leq n'$  and  $d \leq d'$  are nonzero integers, then every  $\phi$ -( $n, d$ ) ring (resp.,  $\phi$ -weak-( $n, d$ ) ring with  $n \geq 1$ ) is a  $\phi$ -( $n', d'$ ) (resp.,  $\phi$ -weak-( $n', d'$ )) ring.*

*Proof.* This is straightforward. □

*Remark 2.15.* Recall that  $\overline{\mathcal{H}}$  is the set of all  $\phi$ -rings whose nilradical is not a maximal ideal. Recall also from [29, Theorem 4.1] that  $R$  is a  $\phi$ -von Neumann regular ring if and only if  $R \notin \overline{\mathcal{H}}$ .

**Theorem 2.16.** *Let  $R$  be a ring. If  $R$  is a  $\phi$ - $(n, d)$  ring, then every  $\phi$ -u-torsion  $R$ -module is  $\phi$ - $(n, d)$ -injective.*

Before proving Theorem 2.16, we establish Lemma 2.17.

**Lemma 2.17.** *Let  $R \in \overline{\mathcal{H}}$  and  $I$  be a finitely generated nonnil ideal of  $R$ . Then  $R/I$  is  $\phi$ -u-projective if and only if  $I = R$ .*

*Proof.* First, we establish that the  $\phi$ -rings are connected. In fact, if there exists a nontrivial idempotent  $e$  in  $R$ , then  $e(1-e) \in \text{Nil}(R)$  implies that either  $e \in \text{Nil}(R)$  or  $1-e \in \text{Nil}(R)$ . But if  $e \in \text{Nil}(R)$ , then  $e = 0$ , which is impossible. Then  $1-e \in \text{Nil}(R)$ , and so  $e \in U(R)$ , which is also impossible. Then  $R$  is connected. On the other hand, we have from [12, Corollary 5.36] that  $R/I$  is a projective  $R$ -module, and so  $I$  is generated by an idempotent by [1, Exercise (10.24)]. Then  $R/I$  is  $\phi$ -u-projective if and only if  $I = R$ .  $\square$

*Proof of Theorem 2.16.* We prove this result for the case where  $Z(R) = \text{Nil}(R)$ . Assume that  $R$  is a  $\phi$ - $(n, d)$ -ring, and let  $N$  be a  $\phi$ -u-torsion  $R$ -module. Then for every  $\phi$ - $n$ -presented module  $R/I$ , where  $I$  is a nonnil ideal of  $R$ , we have that  $\phi\text{-pd}_R(R/I) \leq d$ , and so  $\text{Ext}_R^{d+1}(R/I, N) = 0$  by [12, Theorem 3.10 and Remark 5.3(2)]. Therefore,  $N$  is a  $\phi$ - $(n, d)$ -injective module. Now, if  $Z(R) \neq \text{Nil}(R)$ , then necessarily  $R \in \overline{\mathcal{H}}$ . Lemma 2.17 justifies that  $R/I$  is never a  $\phi$ -u-projective  $R$ -module if we assume that  $I$  is a proper nonnil ideal of  $R$ . We repeat the same previous proof, and we are done.  $\square$

**Theorem 2.18.** *Let  $n \geq 1$  be an integer. Then the following are equivalent for a ring  $R$ .*

- (1)  $R$  is a  $\phi$ -weak- $(n, d)$  ring.
- (2) Every nonnil ideal  $I$  of  $R$ ,  $R/I$  is  $\phi$ - $(n, d)$ -flat.
- (3) Every finitely generated nonnil ideal  $I$  of  $R$ ,  $R/I$  is  $\phi$ - $(n, d)$ -flat.

*Proof.* (1)  $\Rightarrow$  (2) Let  $M$  be a  $\phi$ - $n$ -presented module and  $I$  be a nonnil ideal of  $R$ . By hypothesis, we get that  $M$  has a  $\phi$ -flat dimension at most  $d$ , and so  $\text{Tor}_{d+1}^R(R/I, M) = 0$ . Therefore,  $R/I$  is  $\phi$ - $(n, d)$ -flat.

(2)  $\Rightarrow$  (3)  $\Rightarrow$  (1) These are obvious.  $\square$

**Theorem 2.19.** *If  $R$  is a  $\phi$ - $(n, d)$  ring, then  $R$  is  $\phi$ -weak- $(n, d)$ . The converse holds if  $n \geq d + 1$ .*

*Proof.* Assume that  $R$  is a  $\phi$ - $(n, d)$  ring. Then  $\phi\text{-pd}_R M \leq d$  for every  $\phi$ - $n$ -presented  $R$ -module  $M$ , and so  $\phi\text{-fd}_R M \leq d$ . Therefore,  $R$  is  $\phi$ -weak- $(n, d)$ .

Assume that  $n \geq d + 1$  and  $R$  is a  $\phi$ -weak- $(n, d)$  ring. Let  $M$  be a  $\phi$ - $n$ -presented module with a  $\phi$ - $n$ -finite presentation

$$F_n \rightarrow F_{n-1} \rightarrow \cdots \rightarrow F_0 \rightarrow M \rightarrow 0.$$

Since  $n \geq d + 1$ , it follows that  $K := \ker(F_{d-1} \rightarrow F_{d-2})$  is finitely presented. Moreover  $\text{Tor}_1^R(K, N) \cong \text{Tor}_{d+1}^R(M, N) = 0$  for every  $\phi$ -torsion  $R$ -module  $N$ . So  $K$  is a  $\phi$ -flat module, and so  $K$  is  $\phi$ -u-projective by [12, Theorem 5.13]. Thus  $\phi\text{-pd}_R M \leq d$ , and so  $R$  is a  $\phi$ -( $n, d$ ) ring.  $\square$

**Theorem 2.20.** *Let  $R$  be a ring with  $Z(R) = \text{Nil}(R)$ . If  $R$  is a  $\phi$ -( $n, d + 1$ ) ring, then every factor of a  $\phi$ -u-torsion  $\phi$ -( $n, d$ )-injective module is  $\phi$ -( $n, d$ )-injective.*

*Proof.* Let  $E$  be a  $\phi$ -u-torsion  $\phi$ -( $n, d$ )-injective module. We claim that  $E/N$  is a  $\phi$ -( $n, d$ )-injective module for every submodule  $N$  of  $E$ . First, note that  $N$  and  $E/N$  are  $\phi$ -u-torsion modules. Using the exact sequence  $0 \rightarrow N \rightarrow E \rightarrow E/N \rightarrow 0$ , we get the following isomorphism:

$$\text{Ext}_R^{d+2}(R/I, N) \cong \text{Ext}_R^{d+1}(R/I, E/N)$$

for every  $\phi$ - $n$ -presented module  $R/I$ , where  $I$  is a nonnil ideal of  $R$ . So  $\text{Ext}_R^{d+1}(R/I, E/N) = 0$ , since  $R$  is assumed to be a  $\phi$ -( $n, d + 1$ ) ring. Therefore,  $E/N$  is a  $\phi$ -( $n, d$ )-injective module.  $\square$

**Theorem 2.21.** *Let  $R$  be a ring with  $Z(R) = \text{Nil}(R)$ . If  $R$  is a  $\phi$ -( $n, d + 1$ ) ring, then every submodule of a  $\phi$ -torsion  $\phi$ -( $n, d$ )-flat module is  $\phi$ -( $n, d$ )-flat.*

*Proof.* The proof is similar to the proof of Theorem 2.20.  $\square$

In [12], a  $\phi$ -ring  $R$  is said to be  $\phi$ -hereditary if every nonnil ideal of  $R$  is  $\phi$ -u-projective.

The following result gives some examples of  $\phi$ -( $n, d$ ) rings for small nonnegative integers  $n, d$ .

**Theorem 2.22.** *Let  $R \in \mathcal{H}$ . Then*

- (1)  *$R$  is a  $\phi$ -(0, 0) ring if and only if  $R$  is a  $\phi$ -von Neumann regular ring.*
- (2)  *$R$  is a  $\phi$ -(0, 1) ring if and only if  $R$  is a  $\phi$ -hereditary ring.*
- (3)  *$R$  is a  $\phi$ -(1, 0) ring if and only if  $R$  is a  $\phi$ -von Neumann regular ring.*
- (4)  *$R$  is a  $\phi$ -(1, 1) ring if and only if  $R$  is a  $\phi$ -Prüfer ring with  $Z(R) = \text{Nil}(R)$ .*

To prove Theorem 2.22, we need the following Lemma 2.23. Recall from [12, Definition 5.1] that a short exact sequence of  $R$ -modules

$$0 \rightarrow A \rightarrow B \rightarrow C \rightarrow 0$$

is said to be  $\phi$ -pure exact if for every finitely presented  $\phi$ -torsion module  $F$ , we get the following exact sequence  $0 \rightarrow F \otimes_R A \rightarrow F \otimes_R B \rightarrow F \otimes_R C \rightarrow 0$ . In particular, every pure exact sequence is  $\phi$ -pure. A submodule  $A$  of  $B$  is said to be  $\phi$ -pure if the exact sequence  $0 \rightarrow A \rightarrow B \rightarrow B/A \rightarrow 0$  is  $\phi$ -pure.

**Lemma 2.23.** *Every  $\phi$ -ring  $R$  with  $\phi$ -w. gl. dim( $R$ )  $\leq 1$  is a strongly  $\phi$ -ring.*

*Proof.* Assume that  $\phi$ -w. gl. dim( $R$ )  $\leq 1$  such that  $\text{Nil}(R)$  is not a maximal ideal. If  $\text{Nil}(R) \subsetneq Z(R)$ , then there exists  $s \in Z(R) \setminus \text{Nil}(R)$ . But  $R$  is a

$\phi$ -ring. Then  $R$  is a connected ring, and so  $\frac{R}{\langle s \rangle}$  can not be a  $\phi$ -flat  $R$ -module by [12, Theorem 5.13 and Corollary 5.36]. Then  $\langle s \rangle$  is a  $\phi$ -flat ideal. By [12, Theorem 5.4], the short exact sequence  $0 \rightarrow (0 : s) \rightarrow R \rightarrow \langle s \rangle \rightarrow 0$  is  $\phi$ -pure, which implies that the  $R$ -homomorphism given by  $\varphi : (0 : s) \otimes_R \frac{R}{\langle s \rangle} \rightarrow \frac{R}{\langle s \rangle}$  is an  $R$ -monomorphism. But its kernel equals to  $\frac{\langle s \rangle}{s(0:s)}$ . Then  $\langle s \rangle = s(0 : s)$ , in particular,  $s = rs$  for some  $r \in (0 : s)$ , and so  $s = 0$ , a contradiction. Consequently, we proved that  $Z(R) = \text{Nil}(R)$ .  $\square$

*Proof of Theorem 2.22.* (1)  $R$  is a  $\phi$ -(0, 0) ring if and only if  $\phi\text{-gl. dim}(R) = 0$ ; if and only if  $R$  is a  $\phi$ -von Neumann regular ring by [12, Corollary 5.33].

(2) It follows from Lemma 2.23 and [12, Proposition 5.25] that  $R$  is a  $\phi$ -(0, 1) ring if and only if  $\phi\text{-gl. dim}(R) \leq 1$ ; if and only if  $R$  is a  $\phi$ -hereditary ring by [12, Theorem 4.3].

(3) Assume that  $R$  is a  $\phi$ -(1, 0) ring. If  $R \in \overline{\mathcal{H}}$ , then there exists a finitely generated proper nonnil ideal of  $R$ . By Lemma 2.17,  $R/I$  is never  $\phi$ -u-projective. But  $R$  is a  $\phi$ -(1, 0) ring, then  $\phi\text{-pd}_R(R/I) = 0$ , i.e.,  $R/I$  is  $\phi$ -u-projective, a contradiction. Therefore,  $R$  is a  $\phi$ -von Neumann regular ring by Remark 2.15.

(4) Assume that  $R$  is a  $\phi$ -(1, 1). Then  $Z(R) = \text{Nil}(R)$  by Lemma 2.23. Let  $I$  be a finitely generated nonnil ideal of  $R$ . Then  $\phi\text{-pd}_R(R/I) \leq 1$ , and so  $I$  is  $\phi$ -u-projective. Therefore,  $R$  is a  $\phi$ -Prüfer ring by [12, Theorem 5.41].

Conversely, assume that  $R$  is a  $\phi$ -Prüfer ring, and let  $F$  be a finitely presented  $\phi$ -torsion  $R$ -module. Then  $F$  is a factor of a finitely generated free  $R$ -module  $L$  by a finitely generated submodule of  $L$ , which is  $\phi$ -u-projective by [12, Theorem 5.41], and so  $\phi\text{-pd}_R F \leq 1$ . Therefore,  $R$  is a  $\phi$ -(1, 1) ring.  $\square$

### 3. On $\phi$ - $n$ -coherent rings

In this section, we define a generalization of  $n$ -coherent rings for rings whose nilradical is prime.

**Definition 6.** Let  $n \in \mathbb{N}$ . A ring  $R$  is said to be a  $\phi$ - $n$ -coherent ring if every  $\phi$ - $n$ -presented module is  $\phi$ -( $n + 1$ )-presented.

Recall from [4] that a  $\phi$ -ring  $R$  is said to be  $\phi$ -Noetherian if  $R/\text{Nil}(R)$  is a Noetherian domain, which is equivalent to saying that every nonnil ideal of  $R$  is finitely generated. Recall also from [9] that the 0-coherent rings are exactly the Noetherian rings. The following result gives the analog of this result.

**Proposition 3.1.** *Let  $R \in \mathcal{H}$ . Then  $R$  is a  $\phi$ -0-coherent ring if and only if  $R$  is a  $\phi$ -Noetherian ring.*

*Proof.* Assume that  $R$  is a  $\phi$ -0-coherent ring and let  $I$  be a nonnil ideal of  $R$ . Then  $R/I$  is a finitely generated  $\phi$ -torsion  $R$ -module, and so  $R/I$  is a finitely presented  $R$ -module. Thus  $I$  is a finitely generated ideal. Hence  $R$  is a  $\phi$ -Noetherian ring.

Conversely, assume that  $R$  is a  $\phi$ -Noetherian ring and let  $M$  be a finitely generated  $\phi$ -torsion  $R$ -module. Then  $M$  is finitely presented by [13, Theorem 3.15].  $\square$

Recall from [9] that the 1-coherent rings are exactly the coherent rings. Proposition 3.2 gives the analog of this result.

**Proposition 3.2.** *Let  $R \in \mathcal{H}$ . Then  $R$  is a  $\phi$ -1-coherent ring if and only if  $R$  is a nonnil-coherent ring.*

*Proof.* Assume that  $R$  is a  $\phi$ -1-coherent ring and let  $I$  be a finitely generated nonnil ideal of  $R$ . We claim that  $I$  is finitely presented. First,  $R/I$  is a finitely presented  $\phi$ -torsion  $R$ -module, and so  $R/I$  is a  $\phi$ -2-presented  $R$ -module. Thus  $I$  is a finitely presented ideal of  $R$  by [14, Theorem 2.1.2]. Hence  $R$  is a nonnil-coherent ring.

Conversely, assume that  $R$  is a nonnil-coherent ring and let  $M$  be a finitely presented  $\phi$ -torsion  $R$ -module. Then  $M \cong F/N$ , where  $F$  is a finitely generated free  $R$ -module and  $N$  is a finitely generated submodule of  $F$ . Since  $R$  is nonnil-coherent,  $N$  is a finitely presented module by [13, Theorem 2.6]. So  $R$  is a  $\phi$ -1-coherent ring.  $\square$

To give (counter-)examples, we use the trivial extension. Let  $R$  be a ring and  $E$  be an  $R$ -module. Then  $R \times E$ , called the trivial ring extension of  $R$  by  $E$ , is the ring whose additive structure is that of the external direct sum  $R \oplus E$  and whose multiplication is defined by  $(a, e)(b, f) := (ab, af + be)$  for all  $a, b \in R$  and all  $e, f \in E$ . (This construction is also known by other terminology and other notations, such as the idealization  $R(+E)$  (see [6, 14, 15, 18]).

Recall that in the classical case, if  $R$  is  $n$ -coherent, then every  $n$ -presented module is infinitely-presented. This property does not hold for the  $\phi$ - $n$ -coherent rings. In fact, the ring  $R = \mathbb{Z} \times \bigoplus_{i=1}^{\infty} \mathbb{Q}/\mathbb{Z}$  is an example of a  $\phi$ -Noetherian ring, which is not nonnil-coherent by [13, Example 4.11]. So by Proposition 3.1,  $R$  is  $\phi$ -0-coherent. However, there exists a  $\phi$ -1-presented  $R$ -module that is not  $\phi$ -2-presented. It follows that there exists a  $\phi$ -0-presented  $R$ -module that is not  $\phi$ -2-presented. Therefore, to correct this problem, in the rest of this paper we consider  $(n, d) \in \mathbb{N}^2$  such that  $d \leq n$ .

**Theorem 3.3.** *Let  $R$  be a  $\phi$ - $n$ -coherent ring. Then every direct sum of  $\phi$ -( $n, d$ )-injective modules is  $\phi$ -( $n, d$ )-injective.*

*Proof.* Let  $R$  be a  $\phi$ - $n$ -coherent ring and let  $\{N_i\}_{i \in \Gamma}$  be a family of  $\phi$ -( $n, d$ )-injective modules. Let  $I$  be a nonnil ideal of  $R$  such that  $R/I$  is a  $\phi$ - $n$ -presented module. Then  $R/I$  has a  $\phi$ - $d$ -presentation  $F_d \rightarrow F_{d-1} \rightarrow \cdots \rightarrow F_0 \rightarrow R/I \rightarrow 0$ , since  $d \leq n$ . Because  $R$  is  $\phi$ - $n$ -coherent,  $K_{d-1}$  is a finitely presented  $R$ -module, and so  $\text{Ext}_R^1(K_{d-1}, \bigoplus_{i \in \Gamma} N_i) \cong \bigoplus_{i \in \Gamma} \text{Ext}_R^1(K_{d-1}, N_i)$  by [27, Theorem 3.9.2

(1)]. Then

$$\begin{aligned} \text{Ext}_R^{d+1}(R/I, \bigoplus_{i \in \Gamma} N_i) &\cong \text{Ext}_R^1(K_{d-1}, \bigoplus_{i \in \Gamma} N_i) \\ &\cong \bigoplus_{i \in \Gamma} \text{Ext}_R^1(K_{d-1}, N_i) \\ &\cong \bigoplus_{i \in \Gamma} \text{Ext}_R^{d+1}(R/I, N_i) \\ &= 0. \end{aligned}$$

Therefore,  $\bigoplus_{i \in \Gamma} N_i$  is  $\phi$ -( $n, d$ )-injective. □

**Corollary 3.4.** *If  $R$  is a nonnil-coherent ring, then every direct sum of  $\phi$ -FP-injective modules is  $\phi$ -FP-injective.*

*Proof.* This follows from Propositions 2.4, 3.2 and Theorem 3.3. □

**Theorem 3.5.** *Every  $\phi$ -( $n, d$ )-ring is  $\phi$ - $n$ -coherent.*

*Proof.* If  $n = 0$ , then the theorem is obvious from Theorem 2.22(1) and Proposition 3.1, since every  $\phi$ -von Neumann regular ring is  $\phi$ -Noetherian. Now, assume that  $n \geq 1$  and  $R \in \overline{\mathcal{H}}$ . Let  $M$  be a  $\phi$ - $n$ -presented  $R$ -module. If  $M$  is  $\phi$ -u-projective, then it is projective by [12, Corollary 5.36], and so  $M$  is  $\phi$ -( $n+1$ )-presented. Assume that  $M$  is not  $\phi$ -u-projective. Then by [12, Theorem 3.10], the  $d$ -th syzygy (denoted by  $K$ ) of a finite  $\phi$ - $n$ -presentation of  $M$  is both a finitely presented and  $\phi$ -u-projective  $R$ -module. Again using [12, Corollary 5.36], we get that  $K$  is projective, and so  $M$  is  $\phi$ -( $n+1$ )-presented. Therefore,  $R$  is  $\phi$ - $n$ -coherent. □

**Theorem 3.6.** *Let  $R$  be a  $\phi$ - $n$ -coherent ring and  $N$  be an  $R$ -module. Then  $N$  is  $\phi$ -( $n, d$ )-injective if and only if  $N^+$  is  $\phi$ -( $n, d$ )-flat.*

To prove Theorem 3.6, we need the following lemma.

**Lemma 3.7.** *If  $R$  is a  $\phi$ - $n$ -coherent ring, then for any ring  $T$  and any integer  $d \geq n + 1$ ,*

$$\text{Tor}_{d+1}^R(M, \text{Hom}_T(B, E)) \cong \text{Hom}_T(\text{Ext}_R^{d+1}(M, B), E),$$

where  $M$  is a  $\phi$ - $n$ -presented module,  $E$  is a  $T$ -injective module, and  $B$  is an  $R$ - $T$ -bimodule.

*Proof.* Assume that  $R$  is a  $\phi$ - $n$ -coherent ring and let  $M$  be a  $\phi$ - $n$ -presented module. Then  $M$  is a  $\phi$ - $d$ -presented module with a  $\phi$ - $d$ -presentation

$$F_d \rightarrow F_{d-1} \rightarrow \cdots \rightarrow F_0 \rightarrow M \rightarrow 0.$$

The above exact sequence induces the exact sequence  $0 \rightarrow K_d \rightarrow F_d \rightarrow K_{d-1} \rightarrow 0$ , and so we get the following exact sequence  $\text{Hom}_R(F_d, B) \rightarrow \text{Hom}_R(K_d, B) \rightarrow$

$\text{Ext}_R^1(K_{d-1}, B) \rightarrow 0$ . Thus we get the following commutative diagram with exact rows:

$$\begin{array}{ccccc} 0 \rightarrow \text{Hom}_T(\text{Ext}_R^1(K_{d-1}, B), E) & \rightarrow & \text{Hom}_T(\text{Hom}_R(K_d, B), E) & \rightarrow & \text{Hom}_T(\text{Hom}_R(F_d, B), E) \\ & & \downarrow \cong & & \downarrow \cong \\ 0 \rightarrow \text{Tor}_1^R(K_{d-1}, \text{Hom}_T(B, E)) & \rightarrow & K_d \otimes_R \text{Hom}_T(B, E) & \rightarrow & F_d \otimes_R \text{Hom}_T(B, E) \end{array}$$

Since  $E$  is a  $T$ -injective module, the two vertical right arrows are isomorphisms. Therefore,  $\text{Hom}_T(\text{Ext}_R^1(K_{d-1}, B), E) \cong \text{Tor}_1^R(K_{d-1}, \text{Hom}_T(B, E))$ . Moreover,

$$\begin{aligned} \text{Tor}_{d+1}^R(M, \text{Hom}_T(B, E)) &\cong \text{Tor}_1^R(K_{d-1}, \text{Hom}_T(B, E)) \\ &\cong \text{Hom}_T(\text{Ext}_R^1(K_{d-1}, B), E) \\ &\cong \text{Hom}_T(\text{Ext}_R^{d+1}(M, B), E). \end{aligned} \quad \square$$

*Proof of Theorem 3.6.* This follows directly from Lemma 3.7 using the following isomorphism:  $\text{Tor}_{d+1}^R(R/I, N^+) \cong \text{Ext}_R^{d+1}(R/I, N)^+$  for every nonnil ideal  $I$  of  $R$  such that  $R/I$  is a  $\phi$ - $n$ -presented module.  $\square$

From Proposition 3.2 and Lemma 3.7, we can obviously deduce the following Corollary 3.8.

**Corollary 3.8.** *Let  $R$  be a nonnil-coherent ring and  $M$  be a finitely presented  $\phi$ -torsion module. If  $E$  is an injective  $R$ -module and  $B$  is an  $R$ -module, then we get the following isomorphism:*

$$\text{Tor}_1^R(M, \text{Hom}_R(B, E)) \cong \text{Hom}_R(\text{Ext}_R^1(M, B), E).$$

*Proof.* This follows immediately from Proposition 3.2 and Lemma 3.7.  $\square$

The following definition gives a generalization of  $\phi$ -flat (resp.,  $\phi$ -FP-injective) modules.

**Definition 7.** Let  $R$  be a ring and  $n \in \mathbb{N}^*$ . An  $R$ -module  $M$  is said to be  $\phi$ - $n$ -flat (resp.,  $\phi$ - $n$ -FP-injective) if  $M$  is  $\phi$ -( $n, n-1$ )-flat (resp., nonnil-( $n, n-1$ )-injective).

*Remark 3.9.* Let  $M$  be an  $R$ -module. Then:

- (1)  $M$  is  $\phi$ -1-FP-injective if and only if  $M$  is a  $\phi$ -FP-injective module.
- (2)  $M$  is  $\phi$ -1-flat if and only if  $M$  is a  $\phi$ -flat module.

Next, the following result is the analog of the well-known behavior of [8, Theorem 3.1], which characterizes the  $\phi$ - $n$ -coherent rings.

**Theorem 3.10.** *Let  $R$  be a ring and  $n \in \mathbb{N}^*$ . Then the following are equivalent.*

- (1)  $R$  is  $\phi$ - $n$ -coherent.
- (2) Every direct product of  $R$  is a  $\phi$ - $n$ -flat  $R$ -module.
- (3) Every direct product of  $\phi$ - $n$ -flat  $R$ -modules is  $\phi$ - $n$ -flat.
- (4) Every direct limit of  $\phi$ - $n$ -FP-injective  $R$ -modules is  $\phi$ - $n$ -FP-injective.

- (5)  $\varinjlim \text{Ext}_R^n(M, M_i) \rightarrow \text{Ext}_R^n(M, \varinjlim M_i)$  is an isomorphism for every  $\phi$ - $n$ -presented  $R$ -module  $M$  and every direct system  $\{M_i\}_{i \in \Gamma}$  of  $R$ -modules.
- (6)  $\text{Tor}_n^R(\prod N_\alpha, M) \cong \prod \text{Tor}_n^R(N_\alpha, M)$  for any family  $\{N_\alpha\}$  of  $R$ -modules and any  $\phi$ - $n$ -presented  $R$ -module  $M$ .
- (7) An  $R$ -module  $N$  is  $\phi$ - $n$ -FP-injective if and only if  $N^+$  is  $\phi$ - $n$ -flat.
- (8) An  $R$ -module  $N$  is  $\phi$ - $n$ -FP-injective if and only if  $N^{++}$  is  $\phi$ - $n$ -FP-injective.
- (9) An  $R$ -module  $M$  is  $\phi$ - $n$ -flat if and only if  $M^{++}$  is  $\phi$ - $n$ -flat.
- (10)  $\text{Tor}_n^R(M, \text{Hom}_T(B, E)) \cong \text{Hom}_T(\text{Ext}_R^n(M, B), E)$  for any ring  $T$ , where  $M$  is a  $\phi$ - $n$ -presented module,  $E$  is a  $T$ -injective module, and  $B$  is an  $R$ - $T$ -bimodule.

To prove Theorem 3.10, we need the following lemmas.

**Lemma 3.11** ([8, Lemma 2.9]). *Let  $n$  be a positive integer,  $A$  be an  $n$ -presented  $R$ -module, and  $\{M_i\}_{i \in \Gamma}$  be a direct system of  $R$ -modules (with  $I$  directed).*

- (1) *There is an exact sequence  $0 \rightarrow \varinjlim \text{Ext}_R^n(A, M_i) \rightarrow \text{Ext}_R^n(A, \varinjlim M_i)$ .*
- (2) *There is an isomorphism  $\varinjlim \text{Ext}_R^{n-1}(A, M_i) \cong \text{Ext}_R^{n-1}(A, \varinjlim M_i)$ .*

**Lemma 3.12** ([8, Lemma 2.10]). *Let  $n$  be a positive integer,  $A$  be an  $n$ -presented  $R$ -module, and  $\{N_\alpha\}_{\alpha \in \Gamma}$  be a family of  $R$ -modules.*

- (1) *There is an exact sequence  $\text{Tor}_n^R(\prod N_\alpha, A) \rightarrow \text{Tor}_n^R(N_\alpha, A) \rightarrow 0$ .*
- (2) *There is an isomorphism  $\text{Tor}_{n-1}^R(\prod N_\alpha, A) \cong \prod \text{Tor}_{n-1}^R(N_\alpha, A)$ .*

*Proof of Theorem 3.10.* (1)  $\Rightarrow$  (10) This follows from Lemma 3.7.

(10)  $\Rightarrow$  (7) For  $B := N$ ,  $T := \mathbb{Z}$ , and  $E := \mathbb{Q}/\mathbb{Z}$ , we get that for every  $\phi$ - $n$ -presented  $R$ -module  $M = R/I$ , where  $I$  is a nonnil ideal of  $R$ , we have the following isomorphism  $\text{Tor}_n^R(M, N^+) \cong \text{Ext}_R^n(M, N)^+$ . So  $N$  is  $\phi$ - $n$ -FP-injective if and only if  $N^+$  is  $\phi$ - $n$ -flat.

(7)  $\Rightarrow$  (8) Let  $N$  be an  $R$ -module. If  $N$  is  $\phi$ - $n$ -FP-injective, then  $N^+$  is  $\phi$ - $n$ -flat by hypothesis, and so  $N^+$  is  $\phi$ - $(n, n-1)$ -flat by Definition 7. Thus  $N^{++}$  is nonnil- $(n, n-1)$ -injective by Theorem 2.11. Hence  $N^{++}$  is  $\phi$ - $n$ -FP-injective.

Conversely, assume that  $N^{++}$  is  $\phi$ - $n$ -FP-injective. It follows from [26, Chapter I, Exercise 41] that  $N$  is a pure submodule of  $N^{++}$ , and so  $N$  is  $\phi$ - $n$ -FP-injective by Theorem 2.13.

(8)  $\Rightarrow$  (9) Let  $M$  be an  $R$ -module. By Theorem 2.11 and hypothesis,  $M$  is a  $\phi$ - $n$ -flat module if and only if  $M^+$  is  $\phi$ - $n$ -FP-injective, if and only if  $M^{+++}$  is  $\phi$ - $n$ -FP-injective, if and only if  $M^{++}$  is a  $\phi$ - $n$ -flat module.

(9)  $\Rightarrow$  (3) Let  $\{N_i\}_{i \in \Gamma}$  be a family of  $\phi$ - $n$ -flat modules. By Theorem 2.8,  $\bigoplus_{i \in \Gamma} N_i$  is  $\phi$ - $n$ -flat, so  $(\bigoplus_{i \in \Gamma} N_i)^{++} \cong (\prod_{i \in \Gamma} N_i^+)^+$  is  $\phi$ - $n$ -flat by hypothesis. But  $\bigoplus_{i \in \Gamma} N_i^+$  is a pure submodule of  $\prod_{i \in \Gamma} N_i^+$  by [7, Lemma 1 (1)], and so  $(\prod_{i \in \Gamma} N_i^+)^+ \rightarrow (\bigoplus_{i \in \Gamma} N_i^+)^+ \rightarrow 0$  splits. Thus  $\prod_{i \in \Gamma} N_i^{++} \cong (\bigoplus_{i \in \Gamma} N_i^+)^+$ , and so  $\prod_{i \in \Gamma} N_i^{++}$  is  $\phi$ - $n$ -flat. Since  $\prod_{i \in \Gamma} N_i$  is a pure submodule of  $\prod_{i \in \Gamma} N_i^{++}$  (see [7, Lemma 1 (2)]),  $\prod_{i \in \Gamma} N_i$  is  $\phi$ - $n$ -flat by Theorem 2.13.

(3)  $\Rightarrow$  (2) This is straightforward.

(2)  $\Rightarrow$  (1) Let  $M$  be a  $\phi$ - $n$ -presented with a  $\phi$ - $n$ -finite presentation  $F_n \rightarrow F_{n-1} \rightarrow \cdots \rightarrow F_0 \rightarrow M \rightarrow 0$ . We claim that  $K_{n-1} := \ker(F_{n-1} \rightarrow F_{n-2})$  is a finitely presented  $R$ -module. First, we have the following exact sequence  $0 \rightarrow K_{n-1} \rightarrow F_{n-1} \rightarrow K_{n-2} \rightarrow 0$ . Let  $I$  be an indexing set. Then  $K_{n-2}$  is finitely presented, since  $M$  is  $\phi$ - $n$ -presented, and so  $R^I \otimes_R K_{n-2} \cong K_{n-2}^I$  from [26, Lemma 13.2]. From the following commutative diagram with exact rows:

$$\begin{array}{ccccccc} 0 & \longrightarrow & K_{n-1} \otimes_R R^I & \longrightarrow & F_{n-1} \otimes_R R^I & \longrightarrow & K_{n-2} \otimes_R R^I \\ & & \downarrow & & \downarrow \cong & & \downarrow \cong \\ 0 & \longrightarrow & K_{n-1}^I & \longrightarrow & F_{n-1}^I & \longrightarrow & K_{n-2}^I, \end{array}$$

it follows that  $K_{n-1}$  is finitely presented, and so  $M$  is  $\phi$ -( $n+1$ )-presented. Thus  $R$  is  $\phi$ - $n$ -coherent.

(1)  $\Rightarrow$  (5) This follows immediately from Lemma 3.11(2).

(5)  $\Rightarrow$  (4) This is straightforward.

(4)  $\Rightarrow$  (1) Let  $M$  be a  $\phi$ - $n$ -presented module with a  $\phi$ - $n$ -finite presentation

$$F_n \rightarrow F_{n-1} \rightarrow \cdots \rightarrow F_0 \rightarrow M \rightarrow 0.$$

We claim that  $K_{n-1} := \ker(F_{n-1} \rightarrow F_{n-2})$  is a finitely presented  $R$ -module. Let  $\{N_i\}_{i \in \Gamma}$  be a family of injective modules. Then  $\varinjlim N_i$  is  $\phi$ - $n$ -FP-injective by hypothesis. Hence,  $\text{Ext}_R^1(K_{n-2}, \varinjlim N_i) \cong \text{Ext}_R^n(M, \varinjlim N_i) = 0$ , and so we get the following commutative diagram with exact rows:

$$\begin{array}{ccccccc} \text{Hom}_R(K_{n-2}, \varinjlim N_i) & \longrightarrow & \text{Hom}_R(F_{n-1}, \varinjlim N_i) & \longrightarrow & \text{Hom}_R(K_{n-1}, \varinjlim N_i) & \longrightarrow & 0 \\ \downarrow \cong & & \downarrow \cong & & \downarrow & & \\ \varinjlim \text{Hom}_R(K_{n-2}, N_i) & \longrightarrow & \varinjlim \text{Hom}_R(F_{n-1}, N_i) & \longrightarrow & \varinjlim \text{Hom}_R(K_{n-1}, N_i) & \longrightarrow & 0. \end{array}$$

Therefore, the left two vertical arrows are isomorphisms by [20, Satz 3], and so  $\text{Hom}_R(K_{n-1}, \varinjlim N_i) \cong \varinjlim \text{Hom}_R(K_{n-1}, N_i)$ . Thus  $K_{n-1}$  is finitely presented by [17, Proposition 2.5], and so  $M$  is  $\phi$ -( $n+1$ )-presented. Therefore,  $R$  is a  $\phi$ - $n$ -coherent ring.

(1)  $\Rightarrow$  (6) This follows from Lemma 3.12(2).

(6)  $\Rightarrow$  (3) This is straightforward.  $\square$

By Proposition 3.2 and Theorem 3.10, we can immediately deduce the following result, which characterizes nonnil-coherent rings.

**Corollary 3.13.** *The following statements are equivalent for a  $\phi$ -ring  $R$ .*

- (1)  $R$  is a nonnil-coherent ring.
- (2) Any direct product of  $R$  is a  $\phi$ -flat  $R$ -module.
- (3) Any direct product of  $\phi$ -flat  $R$ -modules is  $\phi$ -flat.
- (4) Every direct limit of  $\phi$ -FP-injective  $R$ -modules is  $\phi$ -FP-injective.

- (5)  $\varinjlim \text{Ext}_R^1(M, M_i) \rightarrow \text{Ext}_R^1(M, \varinjlim M_i)$  is an isomorphism for every finitely presented  $\phi$ -torsion  $R$ -module  $M$  and every direct system  $\{M_i\}_{i \in \Gamma}$  of  $R$ -modules.
- (6)  $\text{Tor}_1^R(\prod N_\alpha, M) \cong \prod \text{Tor}_1^R(N_\alpha, M)$  for any family  $\{N_\alpha\}$  of  $R$ -modules and any finitely presented  $\phi$ -torsion  $R$ -module  $M$ .
- (7) An  $R$ -module  $N$  is  $\phi$ -FP-injective if and only if  $N^+$  is  $\phi$ -flat.
- (8) An  $R$ -module  $N$  is  $\phi$ -FP-injective if and only if  $N^{++}$  is  $\phi$ -FP-injective.
- (9) An  $R$ -module  $M$  is  $\phi$ -flat if and only if  $M^{++}$  is  $\phi$ -flat.
- (10)  $\text{Tor}_1^R(M, \text{Hom}_T(B, E)) \cong \text{Hom}_T(\text{Ext}_R^1(M, B), E)$  for any ring  $T$ , where  $M$  is a finitely presented  $\phi$ -torsion module,  $E$  is a  $T$ -injective module, and  $B$  is an  $R$ - $T$ -bimodule.
